BUNTING, ROSS R., 222.
BURCHMORE, JOHN M., 661.
BURR, H. N., 51.
BYRD, WILLIAM A., 204, 537.

CALDWELL, S. W., 222.
CHASE, S. L., 391.
CHASE, S. B., 418.
CONNELL, G. W., 111.
CORSON, HIRAM, 365.
CRANDALL, CHARLES R., 512.
CURTIS, ROMAINE J., 85.

DALY, W. H., 346.
DE ARMOND, J. A., 584.
DELAFIELD, FRANCIS, 314, 651.
DREYFUS, BRISAC M., 505.
DUHRING, L. A., Clinic, 262.
DUPLAY, M., 253.

ELFERS, JOHN, 229.
ENGEL, HUGO, 27, 145.

FARNHAM, A. E., 585.
FLINT, AUSTIN, 57, 595.
FREUND H. H., 371.
FULLER, C., 443.

GARRETSON, Prof., Clinic, 35.
GAY, NORMAN, 223.
GLASGOW, R. B., 648.
GOODELL, WM., Clinic, 234.

HALE, JAS. I., 644.
HALL, L. B., 566.
HAMILTON, S. M., 165.
HAMILTON, GEO., 285.
HAPPEL, T. J.. 645, 673.
HARDY, M., 589.
HARRIS, T. M., 27, 484.
HATHCOCK, A. M., 54.
HAZZARD, T. L., Report, 65.
HELM, E. C., 584, 585.
HENGST, D. A., 111, 538.
HENRY, FREDERICK, P., 54.
HICKMAN, J. W., 82.
HORNER, FRED., 343.
HUDSON, A. S., 137, 418.
HUDDLESON, JOHN T., 288, 473.
HUTCHINSON, JAS. H., Clinic, 174, 653

JENKINS, GEO. T., 372.

KENNEDY, N. B., 232.
KERLIN, ISAAC N., 533, 561.

LANDESBERG, M., 115.
LAUTENBACH, L. J., Report, 8, 92.
LEVER, J. D. F., 418.
LEVIS, R. J., Clinic, 205.
LITTLE, WM. T., 634.
LYNDON, E. S., 278.

MANLEY, THOS. H., 172.
MANNING. L. S., 421.
MARTIN, W. L., 539.
McCOY, ALEX. W., 313.
M'LANE, JAS. W., 225.
MICHENER, E., 139.
MILLIKIN, J. L., 395.
MITCHELL, CHAS. L., 169.
MONTGOMERY, E. E., 453.
MORRISON, JOSEPH B., 55.
MORRISON, W. H., Report, 67, 119, 625.
MURDOCH, J. B., 431.

NIGHTINGALE, H. B , 363.
NUDING, W. H., 685.

OPPELT, E. A., 252, 584.
OTIS, FESSENDEN N., 113, 141.

PEPPER, WM., Clinic., 625, 671.
PETERS, SAMUEL, 449.
PICKARD, GEO. H., 31.
POLLOCK, C., 616.
PORTERFIELD, FRANK, 26.
POTSDAMER, JOS. B., 424.
PRAEGER, H., 430.
PRINCE, D., 661.
PURYEAR, R. R., 397.

QUIRE, C. E., 443.

RAYMOND, M., 281.
READ, N. S., 398.
REID, J. J., 111.
RIHL, H W., 368.
ROBERTS, JOHN B., 165, 622.

SCHIEDT, PH. M., 507.
SHOLL, EDWARD H., 278, 340.
SHIMONER, A., 540.
SKENE, Prof. A. J. C., 592.
SMITH, T. CURTIS, 477, 617.
SOZINSKEY, THOS. S., 256, 309, 684.
SOUWERS, GEO. F., 9, 78, 107, 426.
STRAWBRIDGE, J. D., 260.
SUTTON, R. S., 472.

TAYLOR, FRED. A., Report, 37, 262.
THOMSON, W., Clinic, 151.
TUCKERMAN, L. B., 53.
TURNBULL, C. S , 331, 387, 463.

VANCE, REUBEN A , 344.
VARIAN WILLIAM, 201.
VOGEL, F. W., 685.

WARREN, C. E., 52.
WAUGH, WM. F., 7.
WHITE, JOHN M., 54.
WIGHT, J. S , 33, 61, 89.
WILLIS, H. F., 190.
WORRALL, THEO. A., 52, 55.

YARROW, H. C., 64.

INDEX.

Abortion, self, 41.
Abdomen; gunshot wound of the, 188; pigmented mole of, 408.
Abdominal cavity, abscess of, 229.
Abnormality in production of hair, 404.
Abscess; treatment of, 13; temperature in acute, 47; of the liver, 65; of the abdominal cavity, 229; of the pancreas, 244; opened antiseptically, 573.
Absence, congenital, of anus and rectum, 237.
Acetate of lead, peritonitis from injection of, 189.
Acid; *carbolic;* as an external application to piles, 27; hypodermic injections of, 232; *chlorhydric*, 220; *salicylic*, 607; *sulphurous,* in diphtheria, 19.
Accidents from pilocarpine in croup, 27.
Aconite; and digitalis, 606; poisoning by, 77, 386; action of, 500.
Action, of aconite 500; of chloroform, 576.
Activities, systemic or local, can two coexist? 684.
Acupuncture in nervous and spasmodic affections, 186.
Acute; abscess, temperature in, 47; articular rheumatism, 132, 628; farcy in man, 384; phthisis, papilloma of the right vocal cord followed by, 424; pneumonia, urine of, 466; miliary tuberculosis, 512; traumatic malignancy, 574; endo-pericarditis, 628.
Addison's disease, 99, 265.
Adenoma of scalp, 160.
Adherent placenta, death from septicæmia, 251.
Adulterated; opium, 188; foods, commissions to examine, 271.
Adulterations, 304, 360, 415, 500.
Africa, South, as a field for practice, 279.
African; treatment of insanity, 580; race, medical education of, 643.
After treatment of lithotrity, 377.
Affection, a rare, 610.
Age of bacilli, the, 682.
Aid association, medical, 343.
Air in hospitals, purification of, 224.
Akido-galvano-cautery for epilation, 105.
Albuminate of mercury in syphilis, 632.
Albuminuria; in pregnancy, 165, 395; factors of, 490.
Alcohol; in diphtheria, 50, 104, 277, 360; in therapeutics, 128; influence of, on diseased conditions, 242.
Alcoholic intoxication, 107.
Alcoholism, juvenile, 95.
Alkaloids derived from protein compounds, 295.
Alkapton in urine, 238.
Alumni; society of University of Penna., 336; association of Jefferson Medical College, 391.
Alveolar osteo-periostitis in diabetes, 301.
Ambulance service in London, 224.
America of the future, 307.
American; diplomas in Australia, 195; illiteracy, from an English source, 252; butter in Ireland, 363; and British Physicians in Paris, 447; work translated into Italian, 476; surgical association, 634; medical association, 661.
Ammonia; muriate of, as an anthelmintic, 20; and peptones in syphilis, 239; poisoning, 466.
Amputation. quadruple, 77.
Amygdalotomy and suicide, 124.
Anacardium poisoning, 362.
Anæmia, miner's, 413.
Anæsthesia, 331; laryngeal, 609.
Anæsthetic, nitrous oxide as an, in labor, 160.
Anæsthetics; reducing fractures without, 137; the working zone of, 185.
Anatomy, physiology, and pathology of the blood corpuscles, 467.
Aneurism; curious case of, 133; of aorta, 624; of the external iliac, 652; of the deep palmar arch, 678.
Ankle joint, diseases of the, 582.
Annual meeting of the Sanitary Council of the Mississippi Valley, 559.
Antagonism of typhoid and intermittent fevers, 27.
Anti-vaccinationists, 139.
Antiseptic; treatment of abscess, 13; properties of essence of wintergreen, 133; ligature of arterial trunks, 604.
Anuria, 43.
Anus; imperforate, 43; and rectum, congenital absence of, 237; artificial, 242.
Aorta, aneurism of, 624.
Apparatus for garroting physicians, 83.
Aphthous stomatitis, local treatment of, 302.
Arsenic, cure of lichen ruber without, 660.
Arsenical; treatment of chorea, 608; poisoning from sardines, 609.
Arterial elasticity, 360; trunks, ligature of, 604.
Arthritis, 677.
Articles of food, testing for lead in, 188.
Articular rheumatism, 132.
Artificial anus, 242.
Ascites, paracentesis in, 627.
Asphyxia in phthisis, death from, 351.
Aspiration; of the bowels in peritonitis, 13; in intestinal invagination, 272.
Assassination, attempted, of Dr. Gray, 336.
Assistant editor, 112.
Asthma; hay, 69; cardiac treatment of, 274.
Asylum, infant, a model, 631.
Asystolism, 281.
Ataxy; locomotor, following small-pox, 190; and sewing machines, 414.
Attempted assassination of Dr. Gray, 336.
Atrophy of the skin, 39.
Atropia, 617.
Atropine, ptyalism in insanity treated by 188.
Australia, American diplomas in, 195.

Bacili, the age of, 682.
Backward a step, 307.
Bacteria as a cause of leprosy, 133.

Bandage, Martin's, 537.
Baron Larry, 194.
Bean calabar, 107.
Bedbug in the ear, 132.
Benign tumors of the breast, removal without mutilation, 463.
Berlin, sanitary exhibition in, 83.
Bethlehem, Pa., smallpox in, 336.
Bidding for practice, 75.
Bilharzia hæmatobia, 404.
Births, multiple, 54.
Bite, snake, treatment of, 413.
Bladder; rupture of the, 210, 461; fungosities cured by scraping the, 573.
Blenorrhœa; treatment of, 31.
Blennorrhagia treated by chlorate of potash, 189.
Blennorrhagic pus, microbi of, 189.
Blood; of animals, infectiousness of, 129; in phthisis, 190; corpuscles, anatomy, physiology, and pathology of the, 467.
Bodies, from the ear, foreign, 41, 386.
Bogus diplomas, 440.
Bones, effects of hereditary syphilis on the, 20.
Book, useful, 195.
Blood letting; should be more frequently employed, 172; in inflammatory diseases, 365.
Boring the ears, 161.
Bougie, a new, 219.
Bowels, in peritonitis, aspiration of the, 13.
Brain; penetrating pistol wounds of the, 99; a remarkable wound of the, 219, 397; gunshot wound of the, 222; concussion of the, 253.
Breasts; excessive development of the 187; removal of tumors of, without mutilation, 463.
Bright's disease; 596; milk diet in, 103; what is it? 246; hypertrophy of the heart in, 302; and rheumatism, 651.
Bristly boy, 237.
British and American physicians in Paris, 447.
Bromides, how to use, 13.
Bromines, topically in chancroids and ulcers, 128.
Bronchitis, 596.
Buildings, school, 382.
Butter, American, in Ireland, 363.
Burns; 584; sucrate of lime liniment for, 188.
Burning of the hygienic exhibition in Berlin, 672.

Cachexia, syphilitic, 381.
Cadavers, preservation of, 165.
Cæsarean section, 414.
Calabar bean, 107.
Calcified adenoma of scalp, 160.
Calcium, unusual effect of the sulphide of, 378.
Calculi, nasal, 271, 386.
Calculus, disintegrated renal, 659.
Canal boat children, 278.
Cancer; the pre-cancerous stage of, 243; of the cervix uteri, 486.
Carbolic acid; as an external application to piles, 27; injections, 232; in diphtheria, 245; poisoning by, 328; or cucumber, 383.
Carcinoma; of the neck of the womb, 234; of the peritoneum and pleura, 595.
Cardiac; hypertrophy and renal disease, 209, 680; asthma, treatment of, 274; dyspnœa, 442.
Caries of the cuboid, 344.
Case; of precocious development, 27; of gout, joints from a, 129; of hernia, 138; of chronic hydrocephalus, 538; of sacculated aneurism, 678.
Cases; of trichinosis, 581; of poisoning from drinking impure water, 653.
Catarrhal fever, 289.
Catheterism, the dangers of, 299.
Cause; of malaria, 77; of conjunctivitis, 301.
Causes; frothing urine and its, 125; of diseases, the nature of, 131.
Cautery, galvano-, for epilation, 105.
Cavity of the abdominal abscess, 229.
Cellulose, digestion of, 684.
Centenarians, 56.
Cerebral lesions in syphilis, 659.
Cerebro spinal meningitis in a newborn infant, 659.
Cerumen, impacted, 426.
Cervix uteri; laceration of the, 453; cancer of the, 486.
Cesspools, 607.
Ceylon, cultivation of cinchona in, 686.
Chancroids and ulcers, bromines in, 128.
Charity; a worthy, 223; organizations, 439.
Chemical causes of life, 608.
Children; school, investigations in regard to, 52; cirrhosis of the liver in, 154; be sent to school, when should, 326; headaches in, 384; young, intertrigo in, 582; newborn, inflammation of the eyes in, 656.
Childbed, temperature in, 182.
Chionanthus, virginica, 633.
Chinese coolies, endemic paraplegia among, 12.
Chloral; hydrate, croton, efficacy of, 14; injections in vomiting, 48.
Chlorate of potash in treatment of blennorrhagia, 189.
Chlorhydric acid, chlorosis treated by, 220.
Chloroform; and ether, death under, 112; the purity of, 218; in cholera, 303; impure, 352; action of, 576; mortality, 679.
Chlorosis treated by chlorhydric acid, 220.
Cholera, chloroform in, 303.
Chordee, new treatment for, 581.
Chorea; 648; from emotional excitement, 42; arsenical treatment of, 608.
Chronic; peritonitis, 20; rhinitis, 21; metritis, 47; kidney disease, 622.
Cigarettes, 77.
Cinchona cultivation; in Jamaica, 223; in Ceylon, 686.
Circumcision; as a sanitary precaution, 76; death from, 328.
Cirrhosis of the liver, 154, 680.
Cirsoid aneurism, 678.
Cleanliness next to godliness, 279.
Clinical; cases of surgical diseases of women, 85; lessons on syphilis, 161; introduction to studies in gynecology, 592.
Cliterodectomy, 105.
Closure of schools, for infectious diseases, 686.
Codeine, value of pure, 358.
Code of Ethics, 644.
College commencements, 334, 391.
Commissions to examine foods and articles of commerce, 271.
Compounds, protein, alkaloids derived from, 295.
Compounding a felony, 417.
Complications; of leprosy, 12; of phthisis, 652.
Compound dislocation of the ankle, 441.
Concussion of the brain, 253.
Conditions, influence of alcohol on diseased, 242.
Congenital; gastro-diaphragmatic hernia, 138;

dislocation of tibia, 222; absence of anus, 237; abnormality in production of hair, 404; club foot, 412; fistula in the sacral region, 468; teeth, 610; irideremia, 601; cardiac disease, 680.
Congress, International Medical, 336.
Constipation, treatment of, 200.
Consultations; 446; with homœopaths, 585; why not? 74.
Consumption, 475, 660.
Contagion, pet animals as carriers of, 609.
Contagiousness. post-mortem, of diphtheria, 132.
Contagious; pneumonia, 161, 303, 322; headache, 418.
Contribute to medical journals, how to, 241.
Control of medical education by the government, 411.
Convulsions; 460, 584; uræmic, 212.
Cook rice, how to, 671.
Cornea, ulcers of, 469.
Corn, a grain of, discharged through chest, 219.
Corpuscles of the blood, 467.
Corrections, 634.
Cough; of tuberculosis, 161; whooping, 300.
Croton chloral, hydrate, efficacy of 14.
Croup membranous, 27.
Croupous pneumonia in children, 568.
Cuboid, caries of the, 344.
Cucumber or carbolic acid, 383.
Cultivation of cinchona; in Jamaica, 223; in Ceylon, 686.
Cure; of cancer, prizes offered for, 392 of lichen ruber without arsenic, 660.
Curious; case of aneurism, 133; malformation, 195.
Cuticle, periodical peeling of the, 294.

Damiana, therapeutic effects of, 183.
Danger of administering anæsthetics without witnesses, 185.
Dangers of catheterism, 299.
Darwin memorial fund, 685.
Dead; bodies in supposed criminal cases, 78, 107; and missing for 1881, 83.
Deafness, engine drivers', 76.
Death; during depression of the tongue, 78; from imagination, 78; chloroform, 112; supposed hydrophobia, 195; pyæmia, 236; septicæmia, 251; asphyxia and phthisis, 351.
Delirium tremens, 379.
Dementia and idiocy, 273.
Dental nerve, stretching of the lower, 78.
Dentition, the disorders of primary, 393.
Depression of the tongue, 79
Detection of impure water, 161.
Development; case of precocious, 27; of the breasts, 187.
Diabetes; and malaria, 47: insipidus treated by electricity, 219; alveolar osteo periostitis in, 301; mellitus, 507.
Diagnosis of ovarian tumors, 14.
Diamond cut diamond, 466.
Digestion of cellulose, 684.
Diphtheria; sulphurous acid in, 19; thymol in, 48; alcohol in, 50, 104, 277, 360; peritonitis, due to, 127; post-mortem contagiousness of, 132; investigations into, 195; carbolic acid in, 245; treatment of, 468.
Diphtheritic; contagium, 224; membrane, a new solvent for, 296; paralysis, treatment of 337.
Diplomas; American in Australia, 195; bogus, 440.
Directory for nurses, 474.
Disagreement among physicians, 223.
Discoveries, M. Pasteur's, 610.
Disease; Bright's 103; wool sorters' 154; Paget's, of nipple, 359; producing theatres, 495; of kidneys, 622.
Diseases; of pregnancy, 1, 225; of women, 85: infectious, 134, 162, 220, 248, 275; zymotic, 278; of the lachrymal apparatus, 462; special hospitals for infectious, 546; of the ankle joint, 582.
Disinfectants 303.
Disinfection; of urine, 414; of physicians' instruments, etc., 447.
Dislocation; of tibia, 222; of the ankle, 441; of vertebra, 442.
Dispensary for diseases of the ear, 27.
Dissecting knife, 52.
Does vaccination protect? 661.
Dressing of wounds, 21, 48.
Drinking impure water, poisoning from, 653.
Drugs, insanity from, 518.
Dysentery; hot water injections in, 20; ixora danduca in, 48; epidemic, 645, 673
Dysmenorrhæa, treatment of, 71.
Dyspeptic nurse, 190.
Dyspnœa, 442.

Ears; dispensary for diseases of the, 27; foreign bodies from the, 41, 386; bedbug in the, 132; puncture of the, 436.
Eclampsia, puerperal, 421.
Eczema; rubrum, 37; of the hands, 373; mask treatment of, 414.
EDITORIALS—
A Review of a Year's Work, 17.
The Hygiene of Schools, 45.
The Spread of Smallpox, 45.
Why not Consult with Homœopaths? 74.
Bidding for Practice, 75.
Preparation for Medical Studies, 102.
Milk Diet in Bright's Disease, 103.
Steamer Surgeons, 130.

Endowment of Research, 658.
The Last Six Months, 682.
The Age of Bacilli, 682.
Education; higher medical, 440; medical, of the African race, 643; government control of, 411, 661.
Effects of prolonged bathing, 216.
Elasticity, arterial, 360.
Elbow, splint for fracture of, 398.
Electric lights, hygienic value of, 447.
Electricity; in labor, 46; in diabetes, 219.
Electrization, laryngeal, 469.
Elongation of the lingual nerve, 217.
Emma Abbott and vaccination, 167.
Endemic of paraplegia among Chinese coolies, 12.
Endo-pericarditis, acute, 628.
Enlarged spleen, 385.
Ephidrosis, 103.
Epidemic; of rötheln in Alabama, 340; dysentery, 645, 673.
Epilepsy; produced by reflex irritation, 107; treatment of, 325; premonitions of, 331.
Epileptiform seizures, 351.
Epithelioma; of leg, 123; of the œsophagus, 442; primary, of the tonsil, 468.
Epulis, with profuse hemorrhages, 499.
Ergotine in pharyngitis, 220.
Ergot; in visceral atony, 523; in lead palsy, 359; for enlarged spleen, 385.
Erythema multiforma, 262.
Essays upon the radical cure of cancer, offered for prizes, 392.
Ether and chloroform, 113.
Etherization, fatality of, in chronic kidney disease, 622.
Ethics; in France, 139; code of, 644.
Etiology of malaria, 449.
Eucalyptus globulus in typhoid fever, 98.
Examination of dead bodies, 78, 107.
Excretion of nitrogen by the skin, 633.
Excessive development of the breasts, early n pregnancy, 187.
Excision; of the pylorus, 105; for sacculated aneurism, 678.
Exhibition, hygienic, at Berlin, burned, 672.
Expert testimony, 634.
Experts, opinion of, 112.
External; application of carbolic acid to piles, 27; genitals, iron ring around, 632; iliac, aneurism of the, 652.
Extirpation; of the thyroid glands, 111; of the lungs, 331; of the eye, 545; of the ovaries, for insanity, 575; of a pulmonary hernia, 583.
Extra-uterine fœtation, 94.
Extraction of teeth in pregnant women, 350.
Extravasation of urine, 113, 141.
Eye; osseous degeneration of the, 436; extirpation of the, 545; protector, for use with the monocular microscope, 566; inflammation of, in newborn children, 656.

Factors of albuminuria, 490.
Farcy, acute in man, 384.
Farms, vaccine, 671.
Fashion; vs. health, 76; follies of, 497.
Fatal; disease contracted from a horse, 84; peritonitis from a vaginal injection of acetate of lead, 189.
Fatality of etherization in chronic kidney disease, 622.
Feeding invalids, 685.
Felony, compounding a, 417.
Female doctors in Russia, 252.
Femur; fracture of, 119, 435.
Fever; *catarrhal*, 289; *intermittent*, 499; *malarial*, 81; *rheumatic*, 236; *scarlet*, 567; *typhoid*; 98; phenic acid in, 104; inoculation for, 343; iodine in, 385; *typho-malarial*, so-called, 166; *yellow*, 320.
Fevers; intermittent and typhoid, antagonism of, 27.
Fibroid tumor of the uterus, 111, 432.
Fibrous tumor; of the uterine neck, 265; growing from sacrum, 499.
Filaria; medinensis, 187; sanguinis hominis, 209.
Fistula; 35; external biliary, 463; congenital. in the sacral region, 468.
Flesh worm, 498.
Floating kidney, 321.
Flowers in sleeping rooms, 160, 279.
Fœtation, extra uterine, 94.
Follies of fashion, 496.
Food, testing for lead in articles of, 188.
Forced; feeding in phthisis, 105; suspension of respiration, 418.
Foreign; growth, hemorrhage due to, 129; bodies from the ear, 41, 386; body in œsophagus followed by emphysema, 579.
Fowler's solution in the treatment of tetanus, 204.
Fracture; of vertebræ, 70, 442; of the shaft of the femur, 119; of elbow, splint for, 398.
Fractures, reducing, without anæsthetics, 139.
France; medical ethics in, 139; myopia in, 672.
Frontal headache, iodide of potassium in, 187.
Frothing urine and its causes, 125.
Fund, memorial, of Darwin, 685.
Fungosities of the bladder cured by scraping with the finger, 573.

Fungus, a new, 609.
Future, America of the, 307.

Galen, instruments in the time of, 295.
Gall bladder filled with gall stones, 625.
Gallo-Roman remains, 581.
Galvanic element for the treatment of constipation, 200.
Galvano-cautery, for epilation, 105.
Garroting physicians, apparatus for, 83.
Generation, on the determination of sex in, 484.
Genital irritation, 385, 632.
Germ theory, 158.
Girl, young, ovariotomy in a, 684.
Glycosuria, 64.
Godliness, cleanliness next to, 279.
Gonorrhœa in the male, 169, 197.
Gout, 129-279.
Government, control of medical education, 411, 661.
Grafting, sponge, 657.
Grain of corn discharged through the chest, 219.
Green oysters, 279.
Grindelia robusta, 244.
Gross; Professor S. D., 410; professorship of pathological anatomy, 644.
Guilds of health, 363.
Gunshot wound; of the abdomen, 188; of brain, 222.

Hair; follicles in the nose, 106; nits in the, 245.
Hæmatology, 160.
Hæmoglobinuria, 267.
Half knowledge, 307.
Halfpenny swallowed by a child and vomited five weeks afterward, 268.
Hay fever, prevention of, 107.
Heads, sizes of, 195.
Headache; 187; contagious, 418
Headaches; in children, 384; sick, 477.
Health; of New York, 77; a psalm of, 195; guilds of, 363.
Heart sounds, reduplication of, 96.
Hemorrhage; 408; due to foreign growth, 129; profuse, 499; transfusion of saline solutions in, 659.
Hereditary; syphilis, effects of, on the bones, 20; lead poisoning, 633.
Heredity, 685.
Hernia; case of, 138; of the ovary, 349; strangulated, 407; extirpation of a pulmonary, 583; inguinal, 677.
Herpes as an underlying cause of other diseases, 180.
Higher medical education, 356, 440.
Hints for the diagnosis of ovarian tumors, 14.
Hoang-nan and hydrophobia, 360.
Homicide by infection, 406.
Homœopaths, consultations with, 74, 585.
Hospital Reports—
  Bellevue Hospital, New York—
    Clinic of Austin Flint., M.D., 595.
  College of Physicians and Surgeons—

  Western Pennsylvania Hospital, 65, 207, 346, 431.
Hospitals; purification of air in, 224; for infectious diseases, 546.
Hot water injections in the treatment of dysentery, 20.
How to cook rice, 671.
Hydatids of the liver, 43.
Hydrate of chloral, 14.
Hydrocele of the neck, 579.
Hydrocephalus, case of chronic, 538.
Hydrophobia; death from supposed, 195; pathology of, 212, 360.
Hygiene; of schools, 45; and public education, 247.
Hygienic; value of electric lights, 447; exhibition at Berlin burned, 672.
Hymen, imperforate, 609.
Hyoscyamia as a depressor motor, 238.
Hypertrophy, cardiac, 209.
Hypopyon, 443,
Hypertrophied heart, 327.
Hypertrophy; of legs, 205; of the heart in Bright's disease, 302; of the prepuce, 414.
Hypnotism, 386.
Hypodermic injections; 21; of quinine, 106; of sulphuric ether, 324; of carbolic acid, 232.
Hysterical retention of urine in a man, 508.

Incontinence of urine, 583.
Idiocy; and dementia, 273; and imbecility, 533, 561.
Idiopathic retro-pharyngeal abscesses, 313.
Ignipuncture, tonsillotomy by, 358.
Iliac, external, aneurism of the, 652.
Illiteracy, American, from, an English source, 252.
Illness caused by filth in milk, 274.
Imagination, a cause of death, 78.
Imperforate hymen, 609.
Impressions, 279, 465.
Impure; water, 161, 653; chloroform, 352.
Incised wound of the skull, 211.
Inconsistency of philanthropists, 686.
Indications for the use of morphia in puerperal eclampsia, 19.
Infant; sucking, inoculation of syphilis by a,

491; asylum, a model, 631; newborn, cerebro-spinal meningitis in, 659.
Infants, hospital for, 586.
Infantile unfoldment, 256.
Infection, homicide by, 406.
Infectious diseases, 134, 162, 220, 248, 275, 546, 686.
Infectiousness of blood and urine of tuberculous animals, 129.
Infectivity of scarlet fever, 575.
Inflammation; of the hair follicles of the nose, 106, 216; of the eyes in new-born children, 656.
Inflammatory diseases, 365.
Influence of alcohol, 242.
Inguinal hernia, 677.
Injections; hot water, 20; hypodermic, 21; in vomiting, 48; of iodoform in syphilis, 273.
Injuries to the nails, 187.
Inoculation; for typhoid fever, 343; for pannus, 294; caused by a sucking infant, 491;
Insanity; 363; a cause for divorce, 139; from drugs, 518, 532; the African treatment of, 580.
Insipidus treated by electricity, 219.
Instances of longevity, 252.
Insurance, by medical men, 572.
Intermittent; fevers, 27; fever and quinine hypodermically, 499.
International; Medical Congress, 336; group, 585.
Interosseous branch of deep palmar arch, aneurism of the, 678.
Intertrigo in young children, 582.
Intestinal invagination, 133, 272.
Intestine, tubercular ulceration of, 497.
Intussusception, 656
Introduction to studies in clinical gynecology 592.
Invalids, feeding of, 685.
Investigations; with regard to school children, 52; into the alleged germ origin of malarial fevers, 96; into diphtheria, 195.
Iodide; of potassium in frontal headache, 187; of potash in pneumonia, 497.
Iodine in typhoid fever, 385.
Iodoform; spray, use of, 190; in orchitis, 245; for soft sores, 467.
Iridæremia, two cases of congenital, 601.
Irish, longevity among the, 167.
Irritation, genital, 385.
Irritating subcutaneous injections of nitrate of silver, 404.
Iron ring around external genitals, 632.
Italian, American work translated into, 476.
Ixora danduca in dysentery, 48.

Jaborandi; 354; and pilocarpine, therapeutic use of, 115; as a diaphoretic, 584.
Jamaica, cultivation of cinchona in, 223.
Joints from a case of gout, 129.
Juvenile alcoholism, 95.

Kangaroo tendons, 330.
Kidney; floating, 321; disease, the fatality of etherization in chronic, 622.
Knee, joint, suppurative synovitis of the, 371.
Knife swallowed by an infant, 359.

Labor; electricity in, 46; nitrous oxide as an anæsthetic during, 160.
Laceration of the cervix uteri, 453.
Lachrymal apparatus, 462.
Larkspur: therapeutic action of, 499.
Laryngeal; diphtheria, 27; electrization, 469 anæsthesia, 609.
Lead; testing for, 188; palsy, ergot in, 359; poisoning, 633.
Leg, epithelioma of, 123.
Legal responsibility of physicians, 298.
Legs, hypertrophy of, 205.

Saturnine neuralgia, 625.
Scalp, calcified adenoma of, 160.
Scarifications, linear, in lupus, 300.
Scarlatina, treatment of, 217.
Scarlatinous virus, permanence of the, 372.
Scarlet fever; in a puerperal woman, cold treatment of, 567; infectivity of. 575.
School children, investigations with regard to, 52, 326, 382.
Schools, hygiene of, 45, 686.
Science, medical, 327.
Scraping, for the cure of fungosities of the bladder, 573.
Scriveners' palsy, 186.
Scrofula and tuberculosis, 273.
Section; cæsarean, 414; of the spinal accessory nerve, 441.
Seizures, epileptiform, 351.
Self abortion, 41.
Sensation of thirst, 246.
Septicæmia; death from, 251; puerperal, 377, 412, 498.
Severe illness caused by ingestion of cakes and cheese, 273.
Sewage water, utilization and purification of, 82.
Sewer gas and puerperal septicæmia, 498.

Sewing machines and ataxy, 414.
Sex, determination of, in generation, 484.
Shaft of the femur, fracture of, 119.
Sick; men, should they be hung? 159; headaches 477.
Signs of pregnancy, 442.
Silver, nitrate, injections of, 404.
Simple mitral stenosis, 505.
Sir Robert Christison's successors, 364.
Sizes of heads, 195.
Skin; atrophy of, 39; grafting, 106; pigmented spots on, 301; excretion of nitrogen by the, 633.
Skull, incised wound of the, 211.
Sleeping rooms, flowers in, 160, 279.
Smallpox; spread of, 45, 222; followed by ataxy, 90; hospitals, 110; and the paper makers; 133; in Philadelphia, 139; a good way to increase, 139; horrors of 139; locomotor ataxy following, 190; pustulation in the fœtus in utero, 245; treated by mustard, 278; and vaccination, 288; disinfectants, 303; in Bethlehem, Pa., 336.
Snake bite, treatment of, 413.
So called typho-malarial fever, 166.
Society, alumni, of Pa. University, 336.
Soda, salicylate of, in variola, 353.
Soft sores, iodoform in, 467.
Solution; mercurial, for hypodermic injections, 21; Fowler's, in tetanus, 204; saline, transfused, in hemorrhage, 659.
Solvent for diphtheritic membrane, 296.
Some; of the practical results of the germ theory, 158; points in the physiology and therapeutics of atropia, 617.
Sounds of the heart, reduplication of, 96.
South Africa as a field for medical practice, 279.
Spasmodic affections, acupuncture in, 186.
Special hospitals for infectious diseases, 546.
Specialism in medicine, 184.
Special Reports—
Management and dressing of wounds, 21, 48.
On the examination of dead bodies in supposed criminal cases, 78, 107.
Infectious diseases, 134, 162, 220, 248, 275.
Adulterations, 304. 360, 415, 500.
Ophthalmology, 331, 387, 469.
Micro germs, 611.
Specific treatment of zoster, 562.
Spinal accessory nerve, section of the, 441.
Spinal nerve, resection of the, 493.
Sphygmograph, 378.
Splenotomy not a justifiable operation in leucocythæmia, 266,
Spleen, enlarged, ergot for, 385.
Splint; for fracture of elbow, 398; plastic, in surgery, 629.
Sponge; tents, 177; grafting, 657.
Spots on the skin, 301.
Spread of smallpox, 45.
Spray, iodoform, use of, 190.
Stage, pre-cancerous, of cancer, 243.
State hospital for women and infants, 586.
Statistics; vital, 112; of consumption, 475.
Steamer surgeons, 130.
Stenosis simple mitral, 505.
Step backward, 307.
Stomach, resection of a portion of, 582.
Stomatitis, aphthous, 302.
Stones in the gall bladder, 625.
Strangulated hernia, 407.
Stramonium, poisoning by, 243.
Stretching; of the lower dental nerve, 78; of nerves in locomotor ataxia, 328.
Studies; medical, preparation for, 102; in gynecology, 592.
Styptic colloid, 223.
Subcutaneous; ligature in varicocele, 68; injections in syphilis, 239, 273.
Subpœnas to medical men, 518
Successful sponge grafting, 657.
Successors to Sir Robert Christison, 364.
Sucking infant, inoculation by, 491.
Sucrate of lime liniment for burns, 188.
Sudden death during depression of the tongue, 78.
Suicide, 124.
Sulphate of atropine in ptyalism, 188.
Sulphide; of carbon and iodoform in phagedænic ulceration, 245; of calcium, unusual effect of, 378.
Sulphuric ether, hypodermic injections of, 324.
Sulphurous acid in the treatment of diphtheria, 19.
Suppurative synovitis of the knee joint, 371.
Supposed; rabid dogs, treatment of wounds from, 19; criminal cases, examination of dead bodies in, 78, 107; hydrophobia, death from, 195; ovarian neuralgia, 441.
Suppositories, nutrient, 330.
Surgeons; for steamers, 120; railroad, 438.
Surgery; oral, 247; modern, 331; aids music, 363; plastic, splints in, 629.
Surgical; diseases of woman, 85; instruments in the time of Galen, 295.
Susceptibility to variola, 26.
Suspension, forced, of respiration, 418.
Swallowing; a halfpenny, 268; a knife, 359.
Sweats, night, picrotoxine in, 54; in phthisis, 405; red, 516.
Switzerland, obligatory vaccination in, 224.
Sympathetic ophthalmia, 151.
Synovitis of the knee joint, 371.
Syphilis; hereditary, its effects on the bones, 20; lessons on, 161, 488; can a man have it twice, 210; from epidermic grafting, 218; treated by subcutaneous injections of mercury, peptones and ammonia, 239; of iodoform, 273; albuminate of mercury in, 632; cerebral lesions in, 659.
Syphilitic; gumma, 93; stricture of the rectum, 181; cachexia 381; diseases of the lachrymal apparatus, 462; inoculations caused by a sucking infant, 491.
Syphiloderma, 457.
Systemic activities, can two coexist, 684.

Tannin in chronic metritis, 47.
Talipes varus, 8.
Teeth; extraction of, in pregnant women, 350; congenital, 610.
Temperature; in acute abscess, 47; in childbed, 182.
Temperatures, high local, 127.
Tendons, kangaroo, 330.
Tents, sponge, 177.
Test for pepsin, 223.
Testicle, undescended, 632.
Testimonial to Professor Leidy, 671.
Testimony, expert, 634.
Testing for lead in articles of food, 188.

Tetanus; treatment of, 20, 51, 207; traumatic 51, 219, 362.
The; coming sanitary congress at New Castle on Tyne, 279; clock said his time had come, 363.
Theatres, disease producing, 495.
Theory, the germ, 158.
Therapeutic; effects of damiana, 183; of phosphorus, 325; use of jaborandi, 115; action of larkspur, 499.
Therapeutics; alcohol in, 128; resorcine in, 359; of atropia, 617.
Thermometer and its use in medicine, 145.
Thirst, the sensation of, 246.
Thymol in diphtheria, 48.
Thyroid gland, extirpation of by enucleation, 111.
Tibia, dislocation of, 222.
Tinea tonsurans; 92; bald, 516.
Tonic pills, 376.
Tonsil; epithelioma of, 468; sarcoma of, 610.
Tonsillotomy, by ignipuncture, 358.
Topical use of bromines in chancroids and ulcers, 128.
Tracheotomy, 605.
Transfusion, 434, 659.
Transient mania, 132.
Translation of American work into Italian, 476.
Traumatic; ophthalmitis; enucleation, 9; sympathetic ophthalmia, 151; acute malignancy, 574; tetanus, 51, 219, 362.
Treatment; of abscess, 13; of aphthous stomatitis, 302; of blenorrhœa, 31; of blenorrhagia, 189; of asthma, 274; of chlorosis, 220; of chordee, 581; of diabetes, 219; of diphtheria, 19, 468; of diphtheritic paralysis, 337; of dysmenorrhœa, 71; of eczema, 414; of epilepsy, 325; of tetanus, 20, 51, 204, 207; of constipation, 200; of dysentery, 20; of insanity, 580; in lithotrity, 377; of fractured patella, 537; of smallpox, 278; of ozæna, 182; of paralysis, 357; of pemphigus, 323; of pigmented spots on the skin. 301; of ptyalism, 188; of wounds from rabid dogs, 19; of rabies, 329; of scarlatina, 217; of scarlet fever, 567; of snake bite, 413; of syphilis, 239; of scrofulous ulcers of the cornea, 469; of uræmic convulsions, 212; of fractures of the vertebræ, 70; of whooping cough, 300; of yellow fever, 302; of zoster, 502; of stricture, 602: of chorea, 608: of pertussis, 660; of sacculated aneurism, 678.
Tribute to Dr. Pancoast's memory, 336.
Trichinosis, two probable cases of, 581.
Triplets (prolonged labor), 348.
Trophic nerve cells, 33, 61, 85.
True ozæna, 126.
Tubercular ulceration of intestine, 497.
Tuberculosis; 273; cough of, 161; miliary, 368, 512, 651.
Tuberculous animals, infectiousness of blood and urine of, 129.
Tumor; of the breast removed without mutilation, 463; of the uterus, 111, 265, 432; from sacrum, 499.
Twins, locked, 403.
Typhoid; and intermittent fevers, antagonism of, 27; eucalyptusglobulus in, 98; phenic acid in, 104; inoculation for, 343; with complications, 346; iodine in, 385.
Typho-malarial fever, so-called, 166.
Ulceration of intestine, 497.
Ulcer of the rectum, 48.
Ulcers; bromines in, 128; phagedenic, 161; of the cornea, scrofulous, treatment of, 469.
Unfoldment, physical, of infants, 256.
University of Pennsylvania: alumni meeting, 336; recognition of alumni, 495.
Unusual effect of the sulphide of calcium, 378.
Uræmia, pericarditis in, 610.
Uræmic convulsions treated by vapor baths and chloral, 212.
Urethra, malformation of the, 137.
Urine; extravasation of, 113, 141, 143; frothing, 125; of tuberculous animals, infectiousness of, 129; alkapton in, 238; disinfection of, 414; of acute pneumonia, 466; hysterical retention of, in a man, 508; incontinence of, 583.
Use; of bromides, 13; of morphia in puerperal eclampsia, 19; of jaborandi, 115; of the thermometer in medicine, 145; of iodoform spray, 190; of eye protector with the monocular microscope, 566.
Useful book, 195.
Uterine: colic, caused by a leech in the uterus, 190; fibroids, 201, 358.
Uterus; ruptured, 125, 539; removal of, 246, 432; paralysis of, 435; fibrous tumor of, 111, 499.
Utilization of sewage water, 82.

Vaccination; Emma Abbott and, 167; compulsory in Indiana, 447; notes, 252, 288; obligatory in Switzerland, 224; question, 55, 502; does it protect? 661.
Vaccine farms, 671.
Vaccino-tuberculosis and vaccino-syphilis, 322, 473.
Vaccinator, an enterprising, 223.
Vaginal injection of acetate of lead, peritonitis from, 189.
Value; of pure codeine, 358; hygienic, of electric lights, 447.
Vapor baths in uræmic convulsions, 212.
Varicocele and varix, subcutaneous ligature in, 68.
Variola; susceptibility to, 26; salicylate of soda in, 353.
Venereal diseases, prevention of, 447.
Venesection; 577; in pneumonia, 190, 399.
Vertebra; fractures of the, treatment of, 70; fracture and dislocation of, 442.
Vesicant, a new, 659.
Victims of the Ring Theatre in Vienna, 293.
Virus, scarlatinous, permanence of the, 372.
Visceral atony, ergot in, 323.
Vital statistics, 112.
Vivisection, 195, 300, 412.
Vocal cord, papilloma of, followed by acute phthisis, 424.
Vomiting; chloral injections in, 48; of pregnancy, 247; a penny five weeks after swallowing it, 268.
Vowels and consonants, 18.

Warm ox blood in phthisis, 190.
Water; impure; detection of, 161; poisoning from, 653; hot, in dysentery, 20; sewage, utilization and purification of, 82.
Way to increase smallpox, 139.

Weavers, poisoning of, by chromate of lead, 272.
Webbed fingers, 266.
What is Bright's disease? 246.
When; a lady's horse shies, 278; should children be sent to school, 336.
Whooping cough; treatment of, 300; nerve element in, 379.
Why not consult with homœopaths? 74.
Wintergreen, properties of essence of, 133.
Witnesses, danger of administering anæsthetics without, 185.
Woman, puerperal, cold treatment of scarlet fever in, 567.
Womb, carcinoma of the, 234.
Women, surgical diseases of, 85.
Wool sorters' disease, 154.
Work; American, translated into Italian, 476; review of a year's, 17.
Working, zone of anæsthetics, 185.
Worthy charity, 223.
Worm, a flesh, 498.
Wound; of the brain, 99, 219, 222, 397: of the abdomen, 188; of the skull, 211; of left lung, 211.
Wounds; from rabid dogs, treatment of, 19; dressings of, 21, 48.
Wrist drop, 98.
Writers' cramp, or scrivener's palsy, 186.

Xanthopsis, 272.

Year's work, a review of, 17.
Yellow; fever, nature and treatment of, 302; aconite, poisoning by, 386.
Young; children, intertrigo in, 582; girl, ovariotomy in a, 684.

Zone, working, of anæsthetics, 185.
Zoster, specific treatment of, 502.
Zymosis, puerperal, 582.
Zymotic diseases, prevention of the, 278.

Smithsonian Institute

WHOLE No. 1297.] JANUARY 7, 1882. [VOL. XLVI, No. 1.

PRICE $5.00 per YEAR. SINGLE NUMBERS 10 CENTS. ESTABLISHED 1853, BY S. W. BUTLER, M.D

RELIABLE BOVINE VIRUS.

(ABSOLUTELY PURE.)

We have for several years supplied the Medical Profession with **BOVINE VACCINE,** which has given the greatest satisfaction, on account of its purity and reliability, and is very generally used.

We receive **FRESH SUPPLY DAILY,** and can fill orders for large or small quantities at short notice.

We would call special attention to the **LYMPH CONES** (guaranteed pure), as being more convenient and economical than the **Ivory Points,** and will keep for a considerable time. *Circulars giving full description on application.*

IVORY POINTS, 15 cts. each, for less than a Case.

" " $1.00 for Case of 10 Points.

LYMPH CONES, $3.00 each, sufficient for several hundred vaccinations.

Sent by mail on receipt of price.

A MANUAL OF OPHTHALMIC PRACTICE,

BY HENRY S. SCHELL, M. D.,

Surgeon to the Wills Eye Hospital, Ophthalmic and Aural Surgeon to the Children's Hospital, etc.

With 53 Illustrations, Test Types, etc. Price, Cloth, $2.00.

This is a new and valuable work on ophthalmic practice, especially designed for the use of the general practitioner who desires a clear and compact manual of instruction in the management of diseases of the eye.

EXTRACT FROM THE PREFACE.

The object of the writer, in the following pages, has been to state briefly the generally accepted principles of Ophthalmology, and to describe those methods of treatment which he has become accustomed to rely upon from personal experience of their value.

CONTENTS.

CHAPTER I.—Anatomy and Physiology of the Eye. CHAPTER II.—Affections of the Eyelids. CHAPTER III.—Disorders of the Lachrymal Apparatus. CHAPTER IV.—Disorders of the Conjunctiva. CHAPTER V.—The Ophthalmoscope. CHAPTER VI.—Refraction and Accommodation and their Anomalies. CHAPTER VII.—Disorders of the Ocular Nerves and Muscles. CHAPTER VIII.—Diseases of the Cornea and Sclerotic. CHAPTER IX.—Diseases of the Iris, Choroid and Ciliary Body. CHAPTER X.—Diseases of the Crystalline Lens. CHAPTER XI.—Diseases of the Vitreous. CHAPTER XII.—Diseases of the Retina and Optic Nerve. CHAPTER XIII.—Disorders of the Eyeball. CHAPTER XIV.—Diseases of the Orbit.

Lecture.

THE DISEASES OF PREGNANCY.

BY JAMES W. M'LANE, M.D.,
Professor of Obstetrics in the College of Physicians and Surgeons, New York.

Gentlemen :—In my former lecture I called your attention to the hygienic management of pregnancy, and alluded to the treatment proper to be employed for the nausea and vomiting of pregnancy where it exceeds the physiological limit and interferes with nutrition, and constitutes a disease, and also to certain other disorders. This morning I propose to consider those disorders of pregnancy which are most commonly met with, and which require treatment.

As a preliminary observation, I would say that a pregnant woman may suffer from any disease from which any other woman may suffer, and we might in that sense consider among the disorders of pregnancy the eruptive fevers, the continued fevers, pneumonia, chorea, epilepsy, and so on. These diseases, however, do not spring out of the condition of pregnancy, and therefore, should not properly be styled disorders or diseases of pregnancy. The diseases of pregnancy properly speaking, are those diseases which are dependent upon that condition, and which require the treatment to be directed accordingly.

Diarrhœa is one of those conditions. Some women always have diarrhœa at the time they conceive, and they can fix upon the date of conception by the occurrence of this disorder of the bowels. Other pregnant women suffer from diarrhœa, at each period, corresponding to a menstrual epoch. Others still suffer in a similar way whenever they eat anything but the plainest food. Now, in those cases in which diarrhœa is a symptom of conception and is associated with it, and passes off in the course of a day or two, causing no particular disturbance, it requires no treatment. When it occurs at a time corresponding to each menstrual epoch it should be checked with caution, being an expression of nature to get rid of the plethoric condition which exists at that time, and which is manifested in some by nose bleeding, swelling of the feet, etc. The kind of diarrhœa, however, which necessitates treatment is that which is associated with a good deal of pain in the bowels, with non-digestion of food, with a good deal of straining and tenesmus, thus endangering the life of the ovum, in consequence of the extreme susceptibility of the nervous system and the intimate union between the nervous supply of the intestines and of the uterus. Pain may be transmitted from the one to the other, and consequently, that beginning in the intestine may extend to the uterus. Many women have lost the product of conception in consequence of a diarrhœa. Of course, the irritability of the uterus is not so great at the third or fourth month, as in the later months, when the child has nearly reached its full growth, and changes between the uterine wall and the placenta have begun to take place. It is wonderful how little intestinal disturbance will at this time bring on labor. It is for this reason that many physicians, when, according to their calculations, the time for labor has arrived, always give a laxative (usually of castor oil), which produces a certain amount of pain and a fluid movement of the bowels, this pain, after a while, being

referred from the intestine to the uterus, bringing labor on immediately. I have seen this occur over and over again when patients themselves took a laxative at the time they expected to be confined.

Where diarrhœa occurs some weeks after pregnancy it requires treatment, and the treatment should be conducted with a good deal of caution. In the first place, you want to learn whether there is anything in the intestine which is the exciting cause of the diarrhœa. If so, it would be foolish to try to check the diarrhœa and not remove the cause. A mild aperient should be administered, especially if the tongue be furred, and along with the aperient some antacid remedy. If, however, the cause of irritation be not local but simply nervous, it should be quieted by the use of local sedatives, among which none is better for this purpose than the subnitrate of bismuth, in large doses, together with small doses of morphine. This will allay irritation and stop the diarrhœa. In other cases it is far better to give rhubarb and soda, or a small quantity of mercurial chalk, until a healthy condition of the tongue and mucous membrane of the stomach is obtained, and then by proper diet the patient may be brought to a condition in which no further treatment will be necessary.

Alternating with this diarrhœa, we often meet with another condition which prevails in a far greater proportion of cases, namely, constipation of the bowels. All women suffer more or less from constipation, even when not pregnant, and it is due largely to their own indiscretion, their own fault, and partly to the fault of the mother in not properly bringing them up. A child is very much like a hickory switch; you can bend it in almost any direction, and it can be made to remain in that shape permanently. You can bring a child up to have certain habits, and it will keep those habits throughout life. I feel very strongly upon this point, because I see constantly the ill effects upon the health of women of neglecting to bring on regularly a peristaltic action of the intestine with an evacuation of the bowels. We are all creatures of habit. If we get into the habit of doing a certain thing at certain hours of the day, and do it during a number of days, weeks, and months, at those particular hours, it in time becomes a necessity with us, a part of the requirements of our being, which we cannot do without. Such are the habits which are grafted upon men and women by their course in life. Now, the habit of regularly evacuating one's bowels is acquired by going to stool always at a particular hour. If to-day we have a stool at nine o'clock, to morrow at ten, and the next day at some other hour, and so on, it will make no difference soon whether we have a stool during the course of the day at all. I have never seen a man who did not have regular bowels if he went to stool at a certain time every day. Many women, however, say it is absolutely impossible to have a regular time for this thing; that their household duties, the care of their children, etc., will not allow of it. Now, there is no woman who has not some hour, or half hour, or ten minutes, out of the twenty four hours, which she can command. For instance, she can go to stool the last thing before retiring at night, or the first thing on rising in the morning. But by all means have it regular, else very soon the bowels will become constipated.

There is another cause for constipation in pregnancy, besides that of irregularity. The gravid womb sags in the pelvis, and by mechanical pressure bears upon the bowel, and renders it almost flat. If you have an opportunity to make a post mortem examination upon a pregnant woman, at the seventh or eighth month, I would advise you to look at the bowel, and your wonder will be, not that her bowels moved irregularly, but that they ever moved at all. Everything is crowded, the intestine is compressed, and performs its duty with a great deal of difficulty, and fecal matter accumulates in the colon. Pregnant women who have a regular movement of the bowels every day may still be suffering from constipation, for the movement may be taking place through the central track of the colon, while all around it is blocked up by fecal matter, and, therefore, when labor comes on, you may find the rectum completely plugged up by hardened fæces, which are forced down at this time from above, where they have remained for some time. It is necessary to remove this accumulation of fecal matter from the rectum, else at parturition you will have trouble with it. The small, semi-fluid fecal evacuation which has regularly been taking place, passes through a central canal dug out through the middle of the hard and impacted mass in the colon. If women would avoid this condition, probably they would not suffer from hemorrhoids in the later months of pregnancy, or after childbirth, and thus they would be saved a great deal of trouble.

Treatment.—Constipation is one of the most common conditions which will require treatment during pregnancy, though frequently it exists when the patient will not complain to you about it. First of all, inculcate in every patient the habit of regularity in going to stool, especially

in young females, so that they may grow up into decent habits. Then see that the food taken is such as will produce in the intestinal track a certain amount of mere bulk which tends to stimulate the intestine to contract upon it. That is, do not have the food too fine, otherwise the intestine cannot contract upon it and force it along by peristaltic action. Let some wheaten grits, or Graham flour, or other form of food that will not be entirely digested, be taken along with the finer or more purely nutritious foods, and let the patient eat fruit, especially such fruits as are laxative. I am more in favor of controlling this condition by hygienic means than by medicine, though often medicine is required to bring the intestine into a healthy condition. Different fresh fruits may be taken, according to the season at which they ripen, and in the winter there are dried and canned fruits, such as prunes, figs, etc. If the patient be very dyspeptic, these sweetened fruits may generate gas and give rise to flatulent dyspepsia, but there are other fruits which are laxative, and they should be taken as a part of the daily food.

With reference to medicine, it will probably be necessary for you, in many instances, to coax the intestine to contract upon its contents, especially if the habit of the woman has previously been one of constipation. Of course, there are various medicines which have been employed for overcoming constipation, and some physicians have more confidence in one variety than in another. The mineral waters, such as the Hunyadi and the Apollinaris, are good if they will produce an evacuation when taken in small quantity ; but if a patient has to take half a bottle full of Hunyadi in the morning, in order to produce an evacuation of the bowels, other medicines had better be given instead ; but if half a wineglassful will produce the desired effect without causing pain, I know of nothing better. There are other women who cannot take these saline laxatives. You should not give a patient citrate of magnesia for the constipation of pregnancy, for it has to be taken in large quantities, and frequently it will not act at all except on the kidneys as a diuretic.

There are other medicines which may be taken in pill form. Now, what you want is not a purgative, but a laxative, and combined with this, something that will stimulate the intestine to its peristaltic function. If you have a proper amount of secretion taking place, and stimulate the muscular fibres to peristaltic action, the masses of fæces in the intestine will be driven along, producing an evacuation of the bowel. You should not give medicines which produce pain or act as purges, such as elaterium or croton oil, for although they would produce a movement of the bowels, they might also excite the uterus to contraction. You wish to employ a mild and efficient remedy, and one of the best is the resin of podophyllum. An eighth of a grain may be given. If you wish to make a pill you may add to it an agent which has a wonderful influence over the muscular part of the intestine, both in women and in children. I refer to belladonna, which, of course, acts in a very different way from the resin of podophyllum. To the pill of resin of podophyllum, one-eighth of a grain, you may add one-eighth of a grain of the alcoholic extract of belladonna. This is a powerful preparation of belladonna, and it assists the action of the may-apple. You may add to this a small quantity of ipecac, which, in small doses, is a tonic to the mucous membrane of the stomach in dyspepsia, and is also a tonic to the intestine. In some cases you will have to add a small quantity of aloes, and here arises the question whether aloes, because of its supposed tendency to produce hemorrhoids, is a dangerous drug to give a pregnant woman. Many women have hemorrhoids who do not take aloes ; many who take aloes have hemorrhoids ; and many have hemorrhoids and take aloes and get well. Historians tell us that Calvin died of piles brought on by the use of aloes, but as Calvin had many other disorders, it is probable that aloes had very little to do with causing his death. It may be combined with a little soap, and thus makes a very nice laxative. If you wish, you can also add a little of the extract of belladonna, and if thought best, hyoscyamus, and also ipecac.

If the patient is suffering from hemorrhoids and you have to operate upon them, or treat them either before or after labor, I would advise you not to employ aloes. If the anus is perfectly healthy you may give aloes without fear of producing piles ; but if the patient have hemorrhoids it is better, as just said, not to give aloes, but give something that will deplete the hemorrhoidal vein. The bitartrate of potassa, with sulphur, has the power of depleting the hemorrhoidal vessels, and hence that is not only my favorite remedy in this particular condition, but it is also that of many physicians. I would give a patient the old-fashioned mixture of sulphur and molasses ; or, if she prefers, sulphur and honey, adding to this the bitartrate of potassa. Take of sublime sulphur and bitartrate of potash, each half an ounce, and if you wish to make it more strongly purgative, add half an ounce of

the sulphate of magnesia, mix in molasses, take in sugar and water, one or two teaspoonfuls on retiring at night. If that does not produce a soft, pultaceous stool in the morning she should take an equal dose during the day. The hemorrhoidal mass outside will then all disappear and the patient will not be obliged to undergo an operation at the time of labor in order to relieve distention by congestion of the hemorrhoidal vessels.

Associated with this condition, constipation, we often have dyspeptic disturbances, such as an acid form of dyspepsia, which patients call heartburn. After eating an ordinary meal there rises up in the throat a quantity of watery fluid, a secretion from the stomach, which is intensely acid and is associated with pain at the cardiac end of the stomach; hence the peculiar name heartburn. I should say that five women out of every eight or nine suffer more or less from this difficulty during the latter months of pregnancy, and they are very apt to ask for something which will afford relief. I am in the habit of using for this purpose the subnitrate of bismuth, with soda, adding a little of the oxalate of cerium. The above, possibly with the addition of a little powdered cubebs, will almost surely relieve this distressing symptom. If this does not relieve it, then you may consider that it is due to mechanical pressure on the stomach, which will not be entirely relieved until after the uterus has been emptied of the fœtus.

Many women are bothered by excessive salivation. This does not seem to be due to inflammation of the mouth, stomatitis, or mercurial ptyalism. The accumulation of saliva is so great that the patient is compelled either to spit a great deal or to swallow it. There are cases on record in which the accumulation of saliva was enormous. Montgomery, for example, mentions a patient whom he attended at three confinements, in whom the daily quantity of saliva exceeded pints, and at night a dozen towels would be saturated with the fluid running out of the woman's mouth. You will be called upon to do something to relieve this symptom, although it may be only sufficient to give the woman some annoyance. Old writers on obstetrics, a hundred and two hundred years ago, allude to this as a symptom of pregnancy.

The best thing that you can do for this is not to employ the ordinary remedies recommended as mouth washes, but to use atropia in small quantity. A hundredth of a grain of atropia, taken in the form of a pellet, will usually diminish this secretion materially. Then allow the patient to have some kind of lozenge which is astringent. The best that I know of is a lozenge of krameria. As this is too costly to be used by the poor, I would advise for them a weak solution of tannin as a mouth wash, which will cause this annoying symptom to disappear.

In addition to these minor disturbances, many patients, although they may not have been constipated or had diarrhœa, suffer from hemorrhoids. This is one of the most common ailments connected with pregnancy, and proper treatment is usually very easy and gives the patient complete relief. Not until the uterus begins to press pretty severely upon the veins in this part of the body, do these hemorrhoids give trouble, and then they annoy the patient greatly, first at stool, and during half an hour or more after stool. Then they discharge a little blood, and then, as masses varying in size from a chestnut to an English walnut, they appear outside of the anus. These masses are exceedingly tender and sensitive, and if touched with the finger the patient complains bitterly. I have seen a woman obliged to sit on the edge of a chair a whole month prior to labor, on account of the presence of such a mass, which though not larger than a hickory-nut, was exceedingly tender.

The irritation may be so great as to bring on labor. For the purpose of preventing it I know of nothing else so good as that just mentioned in connection with the constipation of pregnancy, that is, the bitartrate of potash with sulphur, and this should be given in quantity sufficient to produce an unformed movement from the bowel once or twice a day, one which will slide out through the anal aperture without irritating or distending the sphincter muscle, and in that way you can deplete these vessels. Then, if the part be inflamed and tender I am in the habit of applying ice, and I think this is far better than its opposite, heat. Many advise sponges wrung out of very hot water and applied to the part. I have always found that ice, by benumbing the sensibility of the part, is of much more benefit. Nor have I ever seen any ills come from its use, such as uterine contraction. It is best applied in the form of lumps put into an india-rubber bag or a bladder, and retained in position by a bandage. For a moment it is slightly sensitive, but almost instantly the part becomes benumbed, and soon after, when you look at the mass, which before was swollen, congested, and painful, you will find that there is just the difference between it as it was before and as it is now, that there is between a large California grape and a small raisin. The mass is now so much diminished in size that

you can push it back into the bowel with the finger. The next time, however, that the patient has a stool it will come down again, and if it becomes strangulated, it will become painful. Use ice then, to relieve swelling and pain, and if necessary, continue its use after delivery. After delivery it is sometimes necessary to incise the mass and turn out the central part; and until this is done it will not get well; but I have not seen any case in which it was necessary to do this during pregnancy. The best way to avoid hemorrhage is to keep the bowels loose by agents which deplete the hemorrhoidal veins, and use proper diet and apply ice. Something soothing, as opium, may also be required. If the patient be not of a highly sensitive, nervous organization, with the sense of smell unduly developed, I would advise you to employ iodoform, and you can tell by the presence or absence of its strong odor, whether or not the patient has used it. Although it fills the whole house with its odor, if the patient will use it, it will be found to be very efficacious, and can be employed freely. If, however, on opening the box, the patient throws it out of the window on account of its offensive smell, I know of nothing else better than an ointment of galls, which is officinal in the U. S. Pharmacopœia, to which may be added a little opium. By these means you can almost entirely relieve this troublesome condition.

Many patients also suffer during pregnancy from leucorrhœa. This leucorrhœa is simply an exaggerated glandular secretion from the vagina, and when it is only moderate in extent, and does not give rise to irritation of the sensitive nerves at the vulvar outlet, so as to produce pruritus, it needs no other treatment than cleanliness. For the relief of leucorrhœa of this sort, if it be excessive, you will, perhaps, in the early months of pregnancy, on making an examination with the speculum, find on the cervix an ulcerated spot which you can touch with nitrate of silver, as at this time such treatment will not interfere with pregnancy. But in the later months you may find the cervix perfectly healthy and yet the secretion almost profuse, as if the patient had gonorrhœa. It irritates the sensitive nerves, causes pruritus and leads to scratching, and the patient at last has an eczema which is exceedingly troublesome. Ordinary cleanliness and washing out the vagina with a solution of borax will do no harm to the uterus. A syringe should not be passed up into the vagina and a current of hot water injected against the cervix; neither should the injection be carried very high, even if cool water be employed. The tube should be carried only an inch and a half, or two inches up into the vagina, which should gently be washed out once or twice a day with the solution; and at night the patient may need a suppository which contains an astringent, such as tannin, or a pledget of lint, which has been soaked in glycerole or tannin, and if pruritus exists, an opiate may be employed. If, however, this secretion is profuse it will probably not entirely disappear before labor. It is due to pressure on the vessels in that part of the body, which interferes with the circulation and excites increased glandular secretion.

We now pass from these, what might be called minor ailments, but which often cause a great deal of distress, to another disease of pregnancy which frequently calls for treatment, and, too, for energetic treatment, in order to save the life of the patient. I refer to what is known as albuminuria. This is one of the conditions which obtain sometimes during pregnancy, concerning which every physician ought to have some decided convictions. Albuminuria is a name which we give to a group of symptoms, among which is the presence of albumen in the urine. But albumen in the urine does not constitute albuminuria. We see cases which might properly be termed albuminuria, in which, perhaps, there is no albumen in the urine until after the occurrence of convulsions. My own impression is, that the disease is much more common in the city than in the country. Many physicians in the country say they never saw a case of it, while others with a good obstetric practice will say they have seen one or two cases, and those, perhaps, not marked ones. But any man with a considerable obstetrical practice in the city is sure to have cases of albuminuria, during the winter months especially, which will require treatment. This group of symptoms, one of which consists in the presence of albumen in the urine, is termed, as said before, albuminuria, and was first recognized in 1843, although many pregnant women, of course, had had albumen in the urine before that date. In some cases the amount of albumen found in the urine is very small, and does not call for treatment, and disappears with the termination of the pregnancy; in other cases the quantity is more, but still moderate; in others it is quite large, and exists with the gravest symptoms, even in early months, which call for the most prompt and efficient treatment, and which, notwithstanding, frequently take the life of the mother and of the child. It does not do to trifle with the albuminuria of pregnancy, and pass it over, as has been done by some writers, and re-

cent ones, too, by some remarks which would lead one to suppose that it is not an important matter. I look upon it as a matter of the greatest importance which is met with in pregnancy, and I think many women lose their lives by its being neglected until it has reached such a degree that it cannot be subdued. and eclampsia comes in and ends the scene. How many women die in convulsions at labor, and on examining the urine it is found to contain albumen, whereas the condition leading to these results, probably existed for months previously!

Pressure, doubtless, is a cause, at least in some degree, of the appearance of albumen in the urine during pregnancy, and hence its occurrence in the later months; but there must be some other cause than mere pressure, for pressure, as from abdominal tumors, etc., often exists and no albumen exists in the urine at all. Moreover, pressure must exist in some degree in every case, whereas albuminuria occurs exceptionally, and in some cases in which it does not appear, the pressure is evidently greater than in some in which it is present. A partial cause of albuminuria consists in nervous irritation, such as produces an excessive quantity of saliva, or vomiting, or intestinal diarrhœa. But nervous irritation alone is not sufficient to account for it; the chief cause is to be found in the condition of the blood produced by the pregnant state. I have already called your attention to the state of the blood during pregnancy, and I trust you will not forget it, since it is one of the most important facts to bear in mind in the treatment of any affection of pregnancy. You will remember that the child is using the mother's circulation, with which to get rid of its own products of decomposition, that the red blood corpuscles are diminished in number, etc.

The symptoms of albuminuria are sometimes brought on by taking cold. I have known a woman to be apparently perfectly well, to ride out in a carriage, shortly afterwards get her feet wet, during the night be seized with a severe pain in the head, present albumen in the urine, be seized with convulsions, and within two days from the development of the first symptom, die. Although the urine had been examined all along, up to the development of the first symptom, and was found to contain no albumen, I believe that the exciting conditions had previously existed, and required only the cold as a direct exciting cause to bring on albuminuria. So women who are not pregnant may go to crowded theatres and breathe air loaded with carbonic acid, and then eat a late, hearty supper, without bringing on convulsions, whereas, during pregnancy, the state of the blood is such that these improprieties are liable to be the direct exciting cause of convulsions.

One of the earliest symptoms of albuminuria is headache, and when this persists day after day during the pregnant state, it should not go unheeded by the physician; the urine should be examined. If you are to attend a woman who is pregnant, you should have her, if she is a primipara, send you a specimen of urine for examination at the third month, and then after that every fortnight. If a multipara, she need not send it before the fifth month. It is but very little trouble to examine the urine chemically, and if it be found to contain no albumen, it will be unnecessary to examine it microscopically. After the eighth month, the urine should be examined every week. Patients may think they are given unnecessary trouble in complying with this rule, but you must remember that when the symptoms of albuminuria develop, convulsions come on, and so on, the physician is the person who is held responsible, and the question will then be asked, has the urine been examined? I would not consent to attend a woman in labor who refused to comply with this rule.

In an acute attack, as after taking cold, you will find the urine smoky in color, secreted in small quantity, and containing a large quantity of albumen, and there will be considerable rigidity of the abdominal wall. An examination with the microscope may reveal nothing but the presence of hyaline casts.

How do you know the woman has not Bright's disease? First, the previous history. Has she ever shown any of the symptoms of Bright's disease previous to pregnancy? Had she headache, visual disorders, gastric symptoms? Was she nervous and unduly excited or depressed? Had she been growing irritable, so that her ordinary household duties made her perfectly wretched, etc.?

Certain points tell in favor of Bright's disease, while certain other points tell in favor of albuminuria brought on by pregnancy. Those which tell in favor of albuminuria during pregnancy are, a scanty secretion of urine, smoky in color, and containing from ten to twenty per cent. of albumen, being evidence of congestion, and rigidity of the abdominal wall. The points which speak in favor of true renal or Bright's disease are, secretion of a large quantity of urine, of a pale, watery-looking appearance, containing a considerable quantity of albumen, with fatty and granular casts, and very little rigidity of the abdominal wall.

In addition to renal symptoms, there will be certain other symptoms in albuminuria, such as headache. The woman will wake up in the morning with a little frontal headache, which, perhaps, will pass off in the course of an hour or two; she will probably be troubled with dreams, and if so, they will be of a terrible, frightful kind. These dreams are significant, especially if they are accompanied by headache. Then there are visual disorders; the patient cannot see so well. I knew a patient who could not see her husband standing at the foot of her bed. They complain of seeing motes, etc., floating in the atmosphere, such as are not there in fact; or, if they close the eyes, they may seem to see persons passing by. One patient told me, that whenever she closed her eyes she saw a procession of soldiers in red uniforms passing by. Another symptom is gastric disturbance. If a woman passes by the period at which she is likely to have gastric disturbance, nausea and vomiting, in the first months, and is then troubled with these symptoms in the morning, such as men have who are suffering from chronic Bright's disease, and with these symptoms there exist others already referred to, you may conclude that it is due to the presence in the blood of irritants which should be gotten rid of by the kidneys, but are not so gotten rid of, because these organs are abnormally busy excreting albumen.

Communications.

LEUCORRHŒA OF PREGNANCY.

BY WILLIAM F. WAUGH, A.M., M.D.,

Professor of Materia Medica, etc., in the Medico-Chirurgical College of Philadelphia.

Although leucorrhœa is merely a symptom, and not in itself a disease, it is frequently the principal point upon which our therapeutics are brought to bear. Dependent upon widely different pathological conditions, it may in any case call for treatment to check the flow.

Every physician who treats this class of disease knows how well he is repaid for the systematic investigation of each case; and what light is thus shed upon its treatment. But such an examination is not to be made in unmarried females, unless treatment of rational symptoms fails; and in some other conditions it is contraindicated formally.

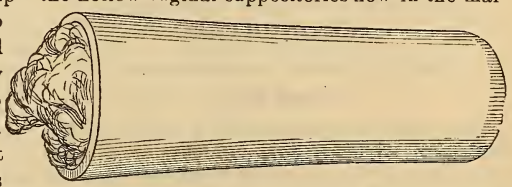
Especially is this true of the leucorrhœa of pregnancy. Here we must lay aside the probe, use the speculum with caution, and may even find the touch difficult if the vagina be abnormally sensitive.

Very often the leucorrhœa is due to gonorrhœa, which is peculiarly apt to be contracted at this period. Catarrh of the cervix is responsible for many cases; and less frequently it is due to relaxation. The ordinary means of treatment are contraindicated. Injections, hot or cold, are unsafe. So, also, are irritant remedies; while the medicated cotton tampon, so valuable at other times, may cause perilous irritation in pregnancy.

The condition of the patient is one of great distress, especially in gonorrhœal cases, where the discharge scalds the vulva and thighs, causing intolerable torment.

To the infant there is the grave danger of ophthalmia neonatorum, from contact with the discharge.

For this condition we have had of late a most valuable therapeutical resource offered to us, in the hollow vaginal suppositories now in the market, manufactured by Dr. C. L. Mitchell, Ninth and Race streets, Philadelphia.



The old suppository of cocoa butter has seen its day. It was filthy and inefficient, quickly melting, while it could not be retained anywhere but just within the vaginal sphincter.

The new preparations (of which the above cut represents the exact size) are composed of gelatine and glycerine (variously medicated), cast in a hollow form, and inserted on a pledget of cotton. They melt slowly, thus medicating the vagina much longer than the cocoa butter.

They are light, and can be readily retained in the upper part of the vagina, while the heavier ones would sink.

Until the suppository is melted, the cotton tampon will not irritate the womb; and when it does, it can be at once withdrawn. Their cleanliness is a recommendation with the patients, which is of value.

It is highly probable, as claimed, that absorption takes place more readily than when the medicine is enveloped in an unctuous material. For these reasons, and especially from the length of time the remedy is kept in contact with the mucous membrane, it follows that this is the most effectual method of treating leucorrhœa

and gonorrhœa yet proposed to the medical public.

I have lately treated three cases of leucorrhœa, two of them gonorrhœal, in pregnant women. The formula I prefer is that which bears the name of Dr. Parker, of Plymouth, Mass. Each suppository contained 10 grs. sulpho carbolate of zinc, and ½ gr. sulphate of morphia. In each case the cure was rapid, safe, and permanent. My patients were pleased with the quick relief following the new treatment, and in no case was there any irritation of the uterus. One of the gonorrhœal cases has since finished the pregnancy, and the child has had no ophthalmia. The others have, as yet, had no return of the leucorrhœa.

UNIVERSITY HOSPITAL.

CLINIC OF D. HAYES AGNEW, M.D.,

Professor of Surgery.

Reported by Louis J. Lautenbach, M.D.

Talipes Varus.

This child, which was before you at our last clinic, has the congenital deformity or defect of club foot, known as varus, talipes varus. The foot is turned in, the heel drawn up. This condition is produced by a loss of power of the extensors of the leg and of the peronei muscles. It is practically a paralysis, these muscles giving way to those situated on the back of the limb.

Such a condition as this must necessarily change the relative articulating surfaces of the bones, and this is followed by a change of the ligamentous connections. The surfaces of the bones are ground off, the edges are rounded, and even the bones and muscles atrophy. Function is interfered with, the movements are restricted, and the weight of the body is supported at a very great disadvantage.

The treatment consists in cutting the tendon of the muscle that holds the foot in the false position. After this is done, we are to keep up a certain amount of manipulation, and sometimes faradism, to prevent the atrophy which is so apt to follow when the muscles are not used.

The peronei muscles are the last to recover. Even when treated in this way they sometimes do not regain their power for two to three years, and then it may occur suddenly; perhaps in a few weeks' time.

Our patient has phimosis, which, while producing many nervous troubles, certainly has nothing to do with club-foot.

The tendo-achillis must be divided subcutaneously. To do this, draw the skin to one side of the tendon, so that after we have cut the tendon and relaxed the skin, the cut in the skin will not correspond to the cut tendon, and thus we have a subcutaneous wound.

Introduce the knife flatwise through the skin behind the tendon, taking care not to wound the posterior tibial artery, which lies in this position; divide the tendon, preferably from below upward, because of the danger which would result to the artery in cutting from above downward, and then by force put the foot in position. Now cover the external wound with a piece of plaster, to prevent the admission of air. On the other foot the same operation is to be performed.

The dressing in cases of this kind is more important than the operation. The treatment now is to keep the foot in its proper position and avoid excoriation. This sometimes fails, as the parts are apt to get sore.

The shoe we use is a modification of the old Scarpa's shoe. It has two movements, both effected by a screw and key. One is to elevate the toe and carry the heel down; the other turns the foot out and retains it in its proper position.

In putting on the apparatus, the heel must rest firmly on the heel of the shoe; if you fail to accomplish this, you fail in your cure. Over the prominence of the great toe we must put a piece of cotton, to prevent pressure. Cotton is also placed above and below the toes. Our patient must keep the shoe on until morning, when it is to be removed and the whole foot rubbed with alcohol until it is in a glow. On the ball of the great toe and at the ankle a piece of lint covered with benzoated oxide of zinc ointment is then to be placed.

If the parts become sore, and there is no necessity that they should, the treatment is apt to fail. It is very important to guard against this condition for the first few days. If the fifth or sixth day be passed without any excoriation, then the treatment will probably be a success.

This shoe extends above the knee. After the shoe is applied, the upper straps, one above the knee, the other at the lower margin of the calf, being buckled, the foot is turned out to its proper position by means of a screw. The toes are now raised, also by means of a screw.

It is sometimes necessary to wear the shoe for two or three years. The time to cease to use it is just that time when the peronei muscles regain their power to contract; but before this time it is not safe to dispense with the apparatus. When, however, the peronei muscles have regained their power, it is to be replaced by a shoe which goes just above the ankle.

Tumor between the Right Breast and Axilla.

The patient, a woman, æt. 24 years, was brought here with the history of a tumor. It is situated on the right side of the right breast, between the breast and the axilla.

The first consideration in the diagnosis is the age, twenty-four years. This eliminates, to a certain degree, the idea of its being malignant. If we speak of a tumor of the mammary gland, or its neighborhood, the inference is that it is a cancer; of course, there are many exceptions to this. When a patient of twenty-four comes to us with a tumor of the breast, we take a favorable view, and are apt to think it not cancer.

This tumor has been growing four years; it is of steady growth; this is important. It is irregular, lobulated; not hard, rather elastic; not

fixed, moves freely. The tendency of malignant growths is to become fixed. The skin can be lifted up from off this tumor; quite important. Carcinoma contracts adhesions to the skin. The tumor slips easily over the muscles, and is not painful; both facts are important, as contrasted with carcinoma.

The average duration of a case of carcinoma in this situation is from two and a half to three years, but there are exceptions to this. This tumor has been growing for four years, and is painless. We can say that it is of a favorable nature for operation, and most probably not malignant. Considered in all its aspects, it is probably an adenoma. We will remove it without touching the breast.

Make a simple incision over the tumor, and it is removed with but one more stroke of the knife. The tumor, from its appearance, is probably but an increase of gland tissue, and when examined microscopically, will probably be found to be an adenoma.

Now, in treating the wound, we do not close it until all bleeding ceases. If necessary, leave it open for fifteen or twenty minutes; but we introduce a silver thread or two while she is still under the influence of ether. Treated in this way, the wound will heal in five or six days.

The great thing in the treatment of a wound is, not to close it until we know positively that all bleeding has ceased. When a wound is so closed it heals very quickly. If we close it, and have a clot ever so small, it undergoes decomposition, followed by the usual lengthy processes of suppuration and healing.

As a dressing, place over the wound lint soaked in carbolized oil, and on this a compress, and on this oakum, which acts as an excellent dressing, being soft, and its odor destroying or masking the odor of the wound. Over this place a broad bandage encircling the chest. To keep the dressing in place, use a T bandage over the right shoulder and around the chest. The arm is then to be fixed across the chest by a sling, and the patient kept perfectly quiet.

Club-foot—Varus, with Bursæ.

This child, somewhat older than our first case, is a subject of the same congenital deformity, but in addition we have bursæ on the outer side of the foot. In consequence of the pressure exerted in walking on the external border of the foot, a condensation of the cellular tissue has been produced, and the formation of a fluid similar to synovial fluid, called bursal fluid. In this case we must treat as in our other case—cut the tendon, elevate the toes, and carry the foot outward.

The father of the child has procured a shoe, but it is not capable of the necessary movements, and, therefore, operative procedure is forbidden until the shoe is rectified.

Nasal Polypi.

This man has suffered with nasal obstruction for twenty five years. The polypi which have been the cause of this have been several times removed, but the obstruction has again returned.

Growths in the interior of the nasal cavity sooner or later produce a deformed nose; it becomes spread and widened, as in this case. The bones, even. by and by, begin to yield. The growth here appears to be a mucous polyp, though this variety does not often cause much deformity.

People who suffer from catarrhal conditions often have growths of this nature. Several mucous glands begin to grow and enlarge, and at length become confluent.

The only thing to do here is to remove them. To-day they will be found to be swollen, due to the moist state of the atmosphere. The mechanism of removing them is by means of a polypus forceps passed into the nostril and catching the growth.

In detaching them, I find here a great deal of resistance due to the fibrous element. Putting the finger behind the palate, some polypi are felt projecting, and I have now, by means of the forceps removed quite a large one which was projecting into the pharynx.

Necrosis on Left Side of the Inferior Maxillary.

This man, who has been etherized, suffers from the effect of the eruption of a wisdom tooth. It is quite apt to cause trouble. The eruption occurs often late in life, when it is apt to result in an abscess, sometimes necrosis. Here it has caused necrosis of the lower jaw, and on introducing the probe through one of the abscess openings the extremity comes in contact with bone, not only dead, but also loose. By extracting the loose pieces we can probably cause the openings to heal up.

The rule in all cases of necrosis of this, as well as of all other bones, is to wait until the sequestrum or dead bone has separated from the living. If you tear it away too quickly, necrosis occurs in the bone from which the piece is torn away.

Looking at this man's left cheek we see two sinuses. Passing in a probe at one of these openings and bringing it out at the other, we cut through all the intervening tissue. Then inserting our forceps, we remove all such pieces of bone which lie loose. Three pieces are all that are loose in this case. All that is now necessary is to simply dress the wound as we would an ordinary open wound.

ST. MARY'S HOSPITAL, PHILADELPHIA.
EYE AND EAR DEPARTMENT.

SERVICE OF H. AUGUSTUS WILSON, M.D,

Surgeon in Charge.

Reported by GEO. F. SOUWERS, M.D.

A Case of Traumatic Ophthalmitis—Enucleation.

We have for consideration to-day the case of J. B., aged 54 years, a steel worker. He represents a type of eye troubles and accidents which the ophthalmic surgeon is continually called upon to treat, and which, if not treated early, promptly, and decisively, terminate in the most disastrous and lamentable results. No consideration should ever induce you to slightingly look over, or manage a case negligently, presenting a history such as is shown by this individual. Such cases as that of this patient all present the same history, differing, perhaps

in a few minor particulars of time, place and incident, but nevertheless. otherwise alike. This person, for instance, tells us that four weeks ago, while engaged in the pursuit of his business, a steel chipping, half an inch in length and three-eighths of an inch in breadth, was forcibly propelled against his right eye. From the phenomena which succeeded, the foreign body undoubtedly impinged upon the cornea, and upon examination, we find this to be the case, for in the upper quadrant of this watch crystal of the eye there is present an oblong cicatrix, its longitudinal axis being vertical. Now, had the force of the blow expended itself at this point, we probably should not have had any further manifestation of the injury than a lacerated wound of the cornea. A greater or less degree of inflammation might have taken place, but this doubtless would have expended its force locally, and not involved surrounding structures in such unfortunate results as we have here to deal with. On examining further, we find that the pupil presents not the rounded appearance that naturally characterizes it, but that it corresponds in shape to the wound in the cornea, vertically oblong, showing thus that some abnormal change has taken place in it. There can be no question as to what this appearance is due to; the force of the missile has wounded the iris and ciliary body, has lighted up an inflammation, which, being left to pursue its own course, has resulted in an inflammatory adhesion of a portion of the iris in the lips of the corneal wound, and there is no force short of absolute rupture of the membrane that can tear it from its new position; earlier in the case atropine would doubtless have exerted its beneficial influence; and though, to-day, even, it might produce more or less stretching and attenuation of the membrane, yet no practical good would result, for the trouble is not so much in the iris as in the ciliary body; a wound of the iris alone might not involve an eye in such profound disturbance and disorganization as we have here to deal with. Upon looking more deeply into the eye we see a cataractous lens, being produced by inflammation communicated from the ciliary body by contiguity of structure.

Coming back to the external portion of this eye, for we cannot examine further back, owing to the condition of the lens just spoken of, we find that the conjunctiva and subconjunctival tissues are deeply injected, lachrymation is excessive, and on pressure the ball is found to be exquisitely sensitive. He tells us that since last Saturday, it being now Thursday, he has suffered unutterable torments, and that he has not been able to gain a moment's sleep, owing to the great pain in the organ.

Now, to what do these indications point? I answer, to but one thing, namely, inflammation of the ciliary body, primarily, and the production of general ophthalmitis of the right eye, with threatened destruction of the uninjured eye. Already there is some supra-orbital pain, slight photophobia, and slightly increased lachrymation of the left eye. Its pupil acts sluggishly, and though this does not of necessity indicate a commencing trouble, yet I should be disposed to narrowly watch such an eye, and to place it under the influence of proper medication. In all cases of traumatism to an eye, with resulting loss of vision, the great danger is a sympathetic involvement of the companion organ; the period of this involvement may be longer or shorter, extending from a few weeks to a number of years. In six cases that I have operated upon, sympathetic ophthalmitis manifested itself in six months, nine and twelve years, and in one case, after thirty-one years had elapsed. Now, this danger does not threaten all eyes alike that have been traumatically blinded; if the foreign body find lodgment in the lens and goes no further, blindness results, it is true, from the production of traumatic cataract, but if the ciliary body and the structures posterior to the lens are not involved, the foreign body may rest in its bed in the lens and give no further trouble. When, however, there is the slightest involvement of the structures beyond the lens, there is a constant threat held over the uninjured eye; sooner or later it sympathizes with its injured fellow and unless promptly treated incurable blindness is the result. Great care must be exercised where cases of traumatic cataract are operated upon, to remove with the lens the irritating foreign body, for otherwise the operation will do more harm than good, and the event sought to be avoided, will be precipitated. The causes operating in the injured eye to produce traumatic blindness are relapsing iridochoroiditis, retinitis, and irido cyclitis. These conditions may, of course, be accompanied by certain attendants, such as intraocular hemorrhage, etc. The question may arise as to how we shall know when the ciliary body has become involved in the injury produced by the foreign body. While perhaps at the time of the accident there is no absolutely reliable symptom as to what has taken place, yet later, the injury may be assumed, if, pressure being made at the upper portion of the ball, pain is experienced. This however, is not a pathognomonic symptom, for it may, indeed, be a sign of some other eye disease; still, if taken in connection with the history of the case, and the seat of injury, it may serve as a means of arriving at a diagnosis. Now before proceeding further, let us pause for a moment to discuss what shall be done in recent cases of foreign bodies that have found entrance into the eye. So long as a useful degree of vision remains, with no complications either of the injured or sound eye, a conservative course must be pursued. The foreign body should be removed if it can be done without doing further damage. If the body is lodged in the cornea, and difficulty is experienced in securing its removal by means of the insufficient size of the opening made by the body, it is a perfectly justifiable proceeding to enlarge the opening to a convenient size, care being taken that the substance be not allowed to drop into the anterior chamber, this being prevented by counter pressure made by means of a delicate needle introduced through the cornea. No gouging of the tissues should be indulged in, in fruitless endeavors to secure the body. One had better desist, than by his manipulations to precipitate violent inflammation. Where the body is very minute, the patient had better be anæsthetized, in order that the operator may be better able to manipulate the eye and govern its motions without experiencing resistance from the patient's

movements. In cases where minute, almost invisible particles of steel and iron constitute the impinging body, it has been suggested that a small magnet be employed to facilitate the removal. When, however, the invading body has penetrated so deeply into the eye as to seriously compromise the acuity of vision, but one step should be taken, and that is the total extirpation of the globe; optico-ciliary neurotomy we shall discuss later. This course should be followed in order to guarantee immunity from danger to the sound eye, and should not be deferred till symptoms of sympathetic ophthalmia make their entrée. The position assumed by the surgeon in the removal of foreign bodies is of importance. He should stand so as to get the most direct and best possible light on the eye. The patient being seated upon a chair in front of such a light, the operator stands behind him, and throwing the head of the patient slightly back, holds the lids out of the way by means of his left hand, or by the stop speculum, the employment of this latter instrument allowing the free use of both hands; a sharp-pointed needle may then be employed to make the removal. If the body do not destroy sight, and if allowed to remain in situ, as before spoken of, a narrow inspection of the eyes must ever afterwards be maintained, in order to nip in the bud any inflammatory symptom, local or sympathetic, that may arise. It is not only eye symptoms that point to the ushering in of sympathetic complications; not they alone which show that the fires of inflammation have again been lighted up, which, unless checked, will go on to produce most dire results. Curious neuralgias, acute dyspeptic and vomiting spells, together with various disturbances of the alimentary tract, not unfrequently, if traced to their source, will be found to owe their origin to a sympathy with an eye about to explode in an ophthalmitis. Indistinct vision is laid down by Mackenzie, as about the first symptom that marks the advent of ophthalmitis in the sound eye, this symptom making its appearance generally in from four to six weeks from the date of the original injury, though it may not transpire for many years. Then pericorneal injection and adhesive iritis follow closely, the pupil becoming, if not closed, very greatly contracted, the vitreous is clouded as well as the cornea, then opacity of the lens follows. These symptoms are accompanied by more or less photophobia; the tension of the eyeball, increased at first, gradually diminishes, and the eye undergoes atrophic changes. Now while this condition is generally the result of the presence of foreign bodies in one eye, yet the condition may be produced by severe blows, and it may even follow the operation for the extraction of cataract. Again Mackenzie has shown that it is not essential that total blindness shall be present in one eye before a sympathetic ophthalmia shall take place in the other. As to what measures of relief should be pursued, I think, after a study of the subject, and a careful weighing of the experience of the profession, that enucleation of the injured eye is the proper treatment to be pursued, for while optico-ciliary neurotomy undoubtedly presents the advantages of preserving a natural tissue in relationship with tissues, of a better cosmetic effect than can be obtained by an artificial eye, yet we well know that nerves having had section made of them, even when pieces had been removed, have a tendency to reunite; in fact, even when the ends have been turned back from each other they have united. If, as is now held, the disease be propagated by means of the ciliary nerves, then when this reunion takes place, we have the same old threat held over the patient's eyes, although Schœler does not admit that this latter portion of the proposition is tenable. I know of at least two cases, where enucleation was necessary after optico-ciliary neurotomy.

Dr. Wm. Thomson beleives that in those cases where division of the optic and ciliary nerves has been performed, good results are obtained by sewing forward the orbital portion of the external rectus muscle to the conjunctiva at the corneal edge, instead of to the tendon, the bulbous extremity of the nerves being thus displaced inwards. I think, however, that the old operation of enucleation is preferable. This is performed by dissecting the conjunctiva up from around the corneal margin; the muscles are then cut off separately close to the eyeball, a pair of scissors passed back deeply into the orbit, and section made of the structures entering the fundus of the eye. The ball being taken out, the conjunctiva and tendons are brought to a point and stitched together in order to make a good stump for an artificial eye; compression is then made on the orbit, by means of cotton wadding or linen cloths kept wet with cold water, and a monocular bandage applied over all. Hemorrhage is not to be feared. It unfortunately happens at times that an artificial eye on this stump sometimes lights up a sympathetic ophthalmia, from the fact that a portion of the cornea or the ciliary nerves may be retained in it; but this is a rare occurrence. As to the time for the operation, I think the best authorities unite in urging its early performance; if sympathetic inflammation has made its debut in the sound eye, the chances are that little benefit will result; still, even then, the patient should be given a chance, for the removal of the source of irritation may, perhaps, suffice to stop the mischief threatened. Unfortunately patients are too often urged to wait, Micawber-like, for something to turn up, and when, alas, that something does turn up, it is too late to prevent total blindness. The performance of an iridectomy is a perfectly useless measure, and is not to be considered in connection with this disease,

Note, ten days later.—An interesting feature in this case was the ecchymosis which followed in the sound eyelids, and was possibly due to vomiting from ether, beginning on the fourth day after the operation. It began on a spot corresponding with point of origin in the right lids, and spread around and resembled accurately the ecchymosis in the lids of the eye operated upon. No further involvement has taken place. The patient has suffered no pain, and but slight inconvenience; the vision in the remaining eye is normal. He was discharged from the house with instructions to return in one week's time, when we will begin the process of hardening the stump preparatory to inserting an artificial eye. I rarely allow the introduction of an artificial eye until one month has elapsed from time of operation.

Editorial Department.

Periscope.

An Endemic of Paraplegia Among Chinese Coolies.

Dr. H. N. Vineberg, of Waiohina, Sandwich Islands, reports, in the *Canada Medical and Surgical Journal*, for November, 1881, the appearance of a peculiar disease among the Chinese laborers on the several sugar plantations on the islands. Of about three hundred coolies employed on the plantations which Dr. V. attends, fully seventy-five have been attacked. The disease often sets in suddenly, the Chinamen dropping down in the field unable to stand. Sometimes the patient's walk is not unlike that of locomotor ataxia when the ataxic muscles are beginning to show signs of motor paralysis. The leg and foot are raised high, brought forward slowly and apparently with an effort, and the whole length of the sole touches the floor at once in completing the step. He walks with his legs wide apart. The muscles feel firm to the touch, and on being tightly grasped by the hand the patient calls out with pain. Tactile sensibility is not impaired, and reflex power is normal. Pain is first referred to the region of the knees and afterwards vaguely to the thighs and legs, but most frequently to the calves only. No pain whatever is referred to the spine, and hard knocks with the knuckles over the spines of the vertebræ elicit no cry of pain. Power over the sphincters of the rectum and bladder is retained to almost the very last. The bowels are usually costive; the appetite is good, and the tongue may be clean or slightly furred. The pulse is frequently from 90 to 110 per minute, and is rather small and compressible. The urine is clear, moderate in amount, and free from albumen. The case may terminate in one of three ways: death, recovery, or pass into a chronic state. In most of the cases ending in death, the paralysis rapidly extends upward, invading the whole muscular frame, the muscles quickly atrophy, and the patient dies asphyxiated, from paralysis of the respiratory apparatus. About 30 per cent. came under this head, and in the greatest number of cases it took place between the third and fourth week. Owing to the superstitions of the Chinese about the dead, the doctor has only been able to hold one *post-mortem*. In that case the lungs, liver, kidneys, spleen, stomach and bowels appeared normal. The mitral valves were thin and small, but showed no signs of inflammatory changes.

Recovery takes place at a variable period, but most often in from three to four weeks, and is liable to be interrupted by several relapses, each of which last from three to four days.

As regards the etiology of this disease the author thinks "Chinese habits," masturbation, etc., with overcrowding and want of proper ventilation, act as predisposing causes. He also states that the diet of coolies consists of rice, peanut oil, bad pork, and semi-putrid sausages. It is more than probable that the putrid meat is the chief cause, as it has been known to produce similar disturbances in Europeans. Moreover, on one plantation, where beef rations were given fresh from the commissariat, no case had occurred. But some time after, while one of the directors was on a visit to the plantation, the Chinese laborers petitioned him to have their beef rations exchanged for its value in money, which was granted to them. They began to indulge freely in their favorite dish, putrid sausages and peanut oil, and in less than three weeks from that date there were no less than thirty cases on that plantation. Again, as soon as the money system was put a stop to and vegetables added to the rations, we had no fresh cases. Connected with the plantations are several small planters who plant corn on shares. They also employ chiefly Chinese coolies, who as a rule have always some vegetables which they grow themselves, and they get their rice and beef served out to them by the planters themselves. None of the planters' coolies have been affected by the disease.

The treatment employed consisted in a generous diet, with vegetables—particularly cabbage; better ventilated and roomy quarters, and stimulants in those cases with a feeble circulation. Stimulating liniments to be well rubbed into the paralyzed limbs, and where the paralysis showed no signs of extending, strychnia and electricity. It is no more than just to say that where this course of treatment was followed out, even if only in part, there the percentage of the cases of recovery was the highest.

On the Complications of Leprosy.

Among the more important complications of leprosy, according to Dr. Henry Dickson Bruns, of New Orleans, in his valuable paper entitled "A Clinical Study of Leprosy," published in the *Archives of Medicine*, for 1881, are bronchitis, indigestion and diarrhœa, which, the author says, are indeed so common that they may rather be styled accompaniments than complications of the disease. The bronchitis of chronic and persistent type is due to congestion, or to the breaking down of tubercles in the mucous membranes of the tubes. The colliquative diarrhœa may be the product of the same causes, or result, as does the indigestion, from the vitiated condition of the blood and the depression of the general health.

Albuminuria is probably, in the majority of cases, due to the invasion of the kidney by the morbid process.

Leprosy predisposes to other affections of the skin. Eczema, elephantiasis Arabum (in countries where it is endemic), herpes zona, impetigo, lichen, molluscum fibrosum, pityriasis, and scabies are all on record as complications. These are worthy of note, for they may, by modifying the appearance of the disease, obscure the diagnosis. Especially is this true of scabies. Indeed, the peculiar changes produced by the presence of the acarus in a leprous skin, led several excellent observers to mistake the nature of this complication, and to declare it an eruption peculiar to leprosy, or, at least—a later opinion—a form of itch found under no other circumstances.

Owing to the state of the skin, the parasite thrives exceedingly well, and small lumps, consisting of masses of thickened epidermis, and countless numbers of the dead insects, are seen upon the hands and other portions of the body.

This disease does not protect against the exanthemata. Cases of variola and varicella have occurred in the persons of lepers in the hospitals at Bergen. Dr. Kaposi quotes from Lawrence (*Jour. Cut. Med.*, vol. I, No. 2, 1867) a case in which measles supervened during the progress of tubercular leprosy. Dr. J. H. Bemiss also gives us to understand that smallpox attacks lepers, and that vaccine matter readily "takes" on them.

Syphilis is only too often found as a coexisting plague in Norway, Sweden, the Hawaiian Islands, and other countries.

Lepers are said to be very susceptible to the influence of cold, and improper food, which renders them especially liable to phthisis, erysipelas and nephritis.

According to Dr. Enders, leprosy in women is usually kept in abeyance so long as menstruation is regularly performed, but the least disturbance of this function may precipitate or aggravate, should it already exist, the disease. This, however, is a *post hoc propter hoc* argument, and it appears to me more than possible that the disturbance of menstruation is rather, as in tuberculosis, an early signal of the approach of a grave constitutional disease.

Lastly, hepatic disorders may arise, in hot climates, toward the end of an attack.

Aspiration of the Bowels in Peritonitis.

A successful instance of this measure is reported by Dr. D M. Williams, in the Dublin *Journal of Medical Science*. The patient was a boy of thirteen. We quote the most interesting part of the history:—

His condition was now alarming; the pulse was, for the first time, irregular and compressible—144 to the minute; breathing very shallow; eyes sunken; cheeks hollow; tongue dry; constantly moaning with pain—evidently dying. He placed his hand on the epigastrium, and said the pain was smothering him, no doubt from pressure upward of the diaphragm interfering with the action of heart and lungs. The abdomen was arched from the xiphoid appendix to pubes, the least attempt at percussion causing great agony. Had not passed water since the 7th. I determined to aspirate him, and passed the finest needle into the transverse colon, and on turning the tap a great quantity of flatus rushed through, followed by three ounces of fluid fæces, which gave him great relief, but did not perceptibly diminish the size of the abdomen. Fearing the needle was blocked, I withdrew it, and found such was not the case. I had evidently emptied this portion of the colon. Having washed the needle, I pierced the ascending colon; another rush of flatus took place, followed by eight ounces of fæces. I repeated the operation on the descending colon, with the same result. There was now very decided diminution of distention and relief of pain: still he complained bitterly of a spot just below the navel, which was quite tympanitic. Taking care to avoid the bladder, I pierced probably the ileum; more flatus escaped, with about half an ounce of fluid fæces. He was now much relieved; pulse had fallen to 96; breathed deeper. 10 P.M. Much the same as after the tapping; expression of face less haggard; pulse 120, full and soft: temperature 102°; passed water freely, and without pain, an hour after the tapping. To take pulv. Doveri, gr. 10, h. s. From this time his progress toward recovery was steady.

Antiseptic Treatment of Abscess.

Dr. Lucas Championnière recommends, in the *Union Médicale*, the following procedure:—

Before opening an abscess, in whatever region it may be placed, we should carefully wash the skin, especially if it has been covered by a poultice, with a strong carbolic acid solution:—

℞. Acidi carbolici,	50 parts
Glycerini,	75 "
Aquæ,	1000 " M.

The bistoury should also be dipped in the solution. The contents of the abscess are to be discharged, and some of the above solution injected, care being taken that the injected liquid has a free issue. The end of a caoutchouc tube is introduced into the wound, having a thread attached to it to facilitate its removal, and it is then covered by a thick layer of charpie, impregnated with a solution of carbolic acid twenty-five parts, glycerine twenty-five parts, and water one thousand parts. Finally, over all is laid a layer of gummed silk. At the end of twenty-four hours the tube is removed in order that it may be cleansed and shortened, when it is again covered with the charpie moistened with the weaker solution. Under this treatment the amount of suppuration is diminished, the redness of the wound becomes insignificant, and the cicatrices which result are much less apparent. Dr. Lucas recommends this procedure especially in abscess of the breast.

How to Use the Bromides.

In an article on the above subject, which appeared in the *Journal of Nervous and Mental Disease*, for July, 1881, Dr. Geo. M. Beard, who, as we all know, is an advocate of heroic (30 to 100 grains or more) doses of this drug, says:

In epilepsy, the necessity of giving doses of considerable size is recognized more and more; but it is not generally allowed, even by neurologists, that in neurasthenia or hysteria doses of even greater size are admissible, proper, and necessary, if we would get the results we seek.

In many cases a single large dose of bromide, say one hundred or one hundred and twenty grains, or even a larger amount, given in a tumbler of water, may be sufficient of itself, without any repetition, in any quantity, to break up an attack of hysteria, or sick headache, or sea-sickness; whereas, the same case in the same condition, treated by divided doses of the same remedy, might not be affected at all.

It sometimes seems to be necessary to overwhelm the nervous system with the sedative effects of the bromide, in order to get bromization.

Although no fatal cases have occurred from these immense doses, dangerous symptoms have been produced by a single dose of one hundred grains. Patients taking bromides should, therefore, be closely watched, and if the medicine has to be continued for any length of time, it should be alternated or combined with tonics, as nux vomica, or, in some cases, ingluvin and arsenic in small doses, to act on the stomach.

Hints for the Diagnosis of Ovarian Tumors.

Dr. A. Macdonald gives the following hints in the Edinburgh *Medical Journal* for November:—

1. *Pregnancy.*—The possibility of pregnancy, the signs and symptoms of pregnancy, and waiting if in doubt, place the diagnosis beyond possible mistake, with a fair measure of care.

2. *Fibroid.*—A large fibroid with solid walls, leading to general enlargement of the uterus, is easily diagnosed. The increased length which the sound enters, the fact that the uterus moves with the sound, the peculiar feel of the uterus, and the nearly constant menorrhagia, suffice to keep the diagnosis correct. It is quite common to hear a bruit in a case of uterine fibroid; only in vascular sarcomata is such audible if the tumor is ovarian. But much greater difficulty is experienced in cases of fibro-cystic tumors connected to the uterus, with or without pedicle. In that case we must try to ascertain whether the tumor is connected or disconnected with the uterus. Then the cyst of a fibro-cystic tumor may be tapped, when we expect to find only a thin fluid of great density, with some blood-corpuscles, and possibly some non-striped muscular fibres. But in those cases it is often found that only an exploratory incision can determine the diagnosis with accuracy.

3. *Renal Cysts* begin below the false ribs and extend downward and forward. They have a line of resonance between them and the liver, due to the transverse colon, which is of value, as showing they are not of hepatic origin, and when aspirated they contain urea. Usually accompanying such there are urinary symptoms, but not always.

4. *Ascites* exhibits the characters of free motion of fluid in an imperfectly filled cavity. Accordingly, when the patient lies on her back the abdomen is flattened anteriorly, the flanks give a dull note, and there is clearness round and above the umbilicus. With change of the patient's position the areas of resonance alter. Thus, if the patient is turned on her left side, the right flank gives a clear note, and *vice versa.* In case of tapping an ascites the thick gelatinous fluid characteristic of ovarian tumor is never obtained.

5. *Hydatid Cyst of the Liver.*—In this case the tumor grows from the liver, distending first the distance between the ensiform cartilage and the umbilicus, the reverse of an ovarian cyst. Again, tapping and discovering acephalocysts in the fluid is convincing evidence of the true nature of the tumor.

6. *Hysterical Abdominal Distention*, commonly known as spurious pregnancy, need deceive no one, as the percussion is uniformly resonant, and the tumor disappears under chloroform.

The Efficacy of Croton-Chloral Hydrate.

It is so long since we saw anything written about this drug that we had almost forgotten its existence. We, therefore, reproduce here the following communication from Dr. Chas. James Fox, of Willimantic, Conn., to the *Medical Bulletin* for December, 1881:—

For some time past I have used, with special efficacy, croton-chloral hydrate in nearly all the cases which have recently come under my observation, of facial neuralgia (some seventeen in all), and my experience in successfully treating the affection by means of the drug have led me to give the results of my observation to the profession. I generally prescribe a full one in this class of cases:—

℞. Croton chloral hydrate, ℥ ij
Glycerine, ℥ ij
Aqua fontana, q. s. ad ℥ iv. M.
Fiat solutio.
Sig.—Ter in die.

In ordinary cases I give a teaspoonful three times a day. If the symptoms are quite urgent, I give a teaspoonful every two hours, until the pain is relieved. In hysteria, especially when convulsions come on, it is specially valuable. My opinion is that the drug, in small doses, produces, first, a næsthesia of the head before the rest of the body is affected. In large doses, the hypnotic effect is marvelous. Suffice it to say, its beneficial value is to be seen in all painful affections of the head, in just such cases. I have observed its efficacy as a therapeutic and remedial agent. Permit me to add, its primary action is clearly marked in producing anæsthesia of the head, and only after this does its influence extend to the organs of the body. Finally, its true value can only be weighed, not by individual experience, but by the general verdict of the profession.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——"Nihilism in Medicine," is the subject of an address delivered before the N. H. Medical Society, June 21, 1881, by Dr. D. W. Jones, of Portsmouth. It comes to us in a reprint from the Society Transactions.

——In a reprint from the New York *Medical Journal and Obstetrical Review*, for November, 1881, Dr. James S. Green gives the history of a case of chronic club-foot successfully treated without tenotomy, by continuous extension and stretching.

——*Godey's Lady's Book* for January, 1882, contains, besides the latest fashions, a large amount of interesting reading matter, a beautiful song, with music, entitled "Birds in the Night," and a fine engraving representing Quentin Durward supporting the Countess Isabelle across the Courts of the Castle of Schonwaldt.

BOOK NOTICES.

Die Krankheiten des Ohres und deren Behandlung. Von Dr. Arthur Hartmann, Aurist, of Berlin. Mit 34 Holzschnitten. Kassel: Verlag. von Theodor Fischer. 1881.

The Diseases of the Ears and their Treatment. By Dr. Arthur Hartmann. 8vo, with 24 illustrations. pp. 212.

This volume has, according to the author, been written for the medical profession at large, not for the specialist, and contains a well digested statement of the diagnosis, prognosis and treatment of diseases of the ear, with the most recent and positive views, avoiding all uncertain and doubtful matters that are still sub judice. The author of this work is well known as one of the youngest of the prominent writers on the subject of diseases of the ear, and yet he has written a number of valuable monographs on various interesting subjects pertaining to this special department of medicine.

The work is evidently intended as a convenient handbook for the medical student, from which he can, at a glance, obtain the most recent modes of treatment freed from all matters of controversy, which, as a rule, take up much valuable space in the works of some of the older German writers. In the preparation of the work our author has availed himself chiefly of the labors of his countrymen, "V. Tröltsch," "Politzer," "Urbantschitsch;" but very few of the English, American, or French writers are even referred to. We are, however, pleased with the work, and give Dr. Hartmann credit for the care and space which he has devoted to the therapeutic portion of the subject, which is usually made subordinate to the other departments.

The introductory seven pages are devoted to an historical account of the ear and its diseases, and is very pleasant reading, giving, as it does, the early rise and progress, and some of the very odd remedies employed for deafness, etc., concluding with full credit to "Itard and Deleau, of France," Wilde and Toynbee, of England, and Lincke and Kramer, of Germany, as the true pioneers in the scientific knowledge and treatment of the diseases of this portion of the human body.

"The recent recognition of the common ground occupied by aural therapeutists and medical practitioners widens the field of otology, and brings the principles of our practice strictly within the domain of general surgery, and relieves them from the ignorant imputations of those misnamed *general surgeons* whose sneers at otology, as a purely empirical department of surgical art, had to be borne with while the etiology and pathology of the obscure affections of this intricate organ were being unraveled by the pioneers in otological science.

"Thanks to the genius and labors of such men as Politzer, Lucca, Gruber, Weber-Liél, Voltolini, Lowenberg, Schwartze, Mayer, and many others on the continent, to Hinton, Cassells, Jones, Woakes and Dalby, of England, and such workers as Turnbull, Burnett, Roosa and Green in the United States, otology has emerged, and can bear, equally with its sister sciences, laryngology and ophthalmology, the light of criticism."*

But to resume the further examination of the work before us, we find chapters first, second, and third, are devoted to the Diagnosis, Symptomatology and Therapeutics, of the Ear. While chapters four, five, six, seven, eight, nine, and ten enter into the consideration of the diseases of the auricle and meatus. Then follow in order the membrana tympani, middle ear, nervous apparatus, and internal ear, concluding with traumatic affections and deaf-muteism; this latter affection being briefly treated, as our author has written a full and comprehensive treatise on this obscure and important subject. The printing of the work is beautiful and clear, and in the Roman type, while the wood cuts, binding, etc., are highly creditable to the publishers.

The Opium Habit and Alcoholism. A Treatise on the Habits of Opium and its Compounds; Alcohol; Chloral Hydrate; Chloroform; Bromide of Potassium and Cannabis Indica: Including their therapeutic indications, with suggestions for treating various painful complications. By Dr. Fred. Herman Hubbard. A. S. Barnes & Co., 111 and 113 William Street, New York. Cloth. 8vo. pp. 259.

After a somewhat sensational depiction of the "rare and pleasing sights" passing before the "waking dreamer," whose mind, inspired by opium, is being "gently carried through fairy lands," enjoying sensations which in their "voluptuous delights" surpass all others, as well as of the "horrible sufferings endured by the confirmed opium eater," the author gives the history of a number of cases, more entertaining than instructive, illustrative of his method of treatment, which consists in the gradual withdrawal of the morphia and the substitution of extract of cannabis indica until the *crisis* comes, over which the patient is carried by means of tonics and baths. He relates a case of opium habit ac-

* Zymosis in Relation to Aural Therapeutics, *Specialist*, Nov. 1881.

quired *in utero*, which came under his care when the child was twenty-six hours old. He began treatment by administering three drachms of paregoric daily, gradually reducing the dose until a cure was effected. We certainly fail to see the wisdom of selecting an alcoholic preparation containing so minute a quantity of opium, unless alcohol was especially indicated. In treating dipsomania, alcoholic preparations of cinchona rubra, cannabis indica, capsicum and ginger, form the chief ingredients of his prescriptions. He also recommends, as an infallible remedy, the thorough seasoning of all foods with a mixture composed of two ounces of whisky, one ounce each of sherry, port, lager beer, cider and champagne, two drachms of gin and one of rum. The chloroform habit, says he, is usually acquired by its use in labor. To remove the necessity of anæsthetics in the lying-in room, he recommends that pregnant women should avoid all foods containing bone-forming elements, in order to starve the fœtus and render its framework yielding and pliable. We have said enough to show the general character of this work. While confined to the professional reader its teachings can do no harm; to the general public they would not only be misleading, but even dangerous. The printing is exceedingly bad and the orthography worse.

A System of Surgery, Theoretical and Practical. In Treatises by Various Authors. Edited by T. Holmes, M.A., Cantab., Surgeon and Lecturer on Surgery at St. George's Hospital, etc., etc. First American from Second English Edition, thoroughly Revised and much Enlarged. By John H. Packard, A.M., M.D., Surgeon to the Episcopal and St. Joseph's Hospital, Philadelphia. Assisted by a large corps of the most eminent American surgeons. In three volumes, with many illustrations. Vol. II, Diseases of Organs of Special Sense; Diseases of Circulatory System; Diseases of Digestive Tract; Diseases of Genito-Urinary Organs. Philadelphia: Henry C. Lea's Son & Co.: 1881. 8vo, pp. 1063.

This volume is divided into four parts, as indicated in the title page. Nineteen subjects are treated of, some of them very exhaustively. Thus one hundred and seventy-one pages are devoted to diseases of the eye, and the subject illustrated with numerous wood-cuts and three beautifully colored chromo-lithographic plates. Diseases of the other organs of special sense likewise receive more attention than is usual in works on surgery. Part II, on diseases of the circulatory system, is especially interesting, on account of the fullness with which aneurisms are treated of, the methods devised for their cure described and reference to numerous cases given. Parts III and IV, which treat of diseases of the digestive tract and of the genito-urinary organs respectively, are very fair representations of our knowledge at the present day. In other respects—the mechanical execution of the work, illustrations, etc.—what we said of the first volume applies equally to this.

The Nurse and Mother; a Manual for the Guidance of Monthly Nurses and Mothers; comprising Instructions in regard to Pregnancy and Preparation for Childbirth, with Minute Directions as to Care during Confinement, and for the Management and Feeding of Infants. By Walter Coles, M.D., Consulting Physician to St. Ann's Lying-in Asylum, St. Louis, Mo. J. H. Chambers & Co., Chicago, Ill., St. Louis, Mo., Atlanta, Ga., 1881. Cloth, 8vo, pp. 153.

The author's chief object in preparing this little manual has been to elevate the nurse above the old superstitions of the lying-in room, by imparting to her satisfactory information concerning all that is necessary for her to know and to do in her capacity as such. The "old and experienced" nurse who has not received the proper training is certainly the most unfit and useless person in a lying-in room, and we sincerely hope that this book will be carefully studied by those who intend to fit themselves for this important calling. They would then understand the proper relations between nurse, patient and physician, and have a sufficient knowledge of pregnancy and labor, together with such accidents as may occur, hemorrhage, etc., calling for immediate measures, to act intelligently, if the medical attendant be absent, and be of valuable assistance if present. The management of the child also receives full attention, and the work seems in every way well adapted to the purpose for which it has been written.

Walsh's Physician's Combined Call-Book and Tablet. Seventh edition. Published by Ralph Walsh, M.D., 332 C street, Washington, D. C. Price $1.50.

Arranged very much on the plan of other similar books, and containing a large amount of such information regarding doses, poisons and antidotes, formulæ for hypodermic injections, inhalations, suppositories and pessaries, period of teeth cutting, disinfectants, urine analysis, post-mortem examinations, medico-legal examinations, treatment of asphyxia from drowning, incompatibles, the pulse, metric weights and measures, etc., etc., as the practitioner may want to look up at a moment's notice, Walsh's Call Book will be found admirably adapted to the wants of the profession. It is handsomely bound in red morocco cover.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

PHILADELPHIA, PA

A REVIEW OF A YEAR'S WORK.

At the opening of the New Year it has been our custom to cast a retrospective glance at the original articles of chief moment which have appeared in the columns of the REPORTER during the preceding twelve months. The custom is a good one, as it serves to recall to many readers what has escaped their memory and what they may be glad to turn to again.

Glancing over the numbers for 1881, the eye is attracted by the numerous contributions on the practical aspect of clinical medicine. We believe no journal in this country could show a richer list. Early in the year two series of articles attracted especial attention. The one was on endocarditis and allied conditions, by Dr. ALONZO CLARK, of New York, the other, on pneumonia and its treatment by venesection, by Dr. HIRAM CORSON. The latter prompted numerous replies and discussions in the various journals and at many societies. The treatment and varieties of nasal catarrh elicited several articles, by Drs. C. S. TURNBULL (Feb. 19th), GUSTINE (Feb. 26th), and BARTON (April 19th), the latter advocating the advantages of medicated gelatine. The employment of colchicum in acute rheumatism was set forth by Dr. FARNSWORTH (July 2d), and the disease itself discussed by Dr. HORNER (March 19th). Dyspepsia from nervous organic causes was the subject of several articles, by Drs. CRANDALL (May 14th, July 3d) and BIGELOW. The indications and abuses of chloral hydrate and opium were set forth in a number of contributions by Dr. KANE (January 29th, May 14th, etc.) SOUWERS (Nov. 12th, etc.), and other writers. The papers of Dr. HILL, on headache (July 23d), STONE on rœtheln (April 30th), BELL on malaria (Feb. 5th), LEE on the Swedish movement cure (Feb. 19th), and especially the careful study of the cause and character of the diphtheritic poison, by Dr. EVERETT (August 20th, 27th), will not have passed from the memory of readers.

The Diseases of Children have been discussed in various able essays, of which we mention that of Dr. MORRIS, on incontinence of urine in boys (June 11th), Dr. REED, on icterus neonatorum (March 26th), Dr. SIMON on typhoid fever in children (March 12th), etc.

Turning to Gynecology and Obstetrics, we select as specially noteworthy, Dr. BEVERLY COLE'S paper on the mechanical treatment of uterine displacements (June 4th), Dr. WOODWARD on coccygodynia (Oct. 8th), Dr. WATHEN on vesico vaginal fistula (Feb. 12th), Dr. WALLACE on the use of the forceps (April 2d), Dr. SACKETT on post-partum hemorrhage (Jan. 22d), Dr. DAVIS on placenta prævia (August 13th), Dr. STONE on the management of the perineum in labor (Dec. 3d), etc.

In the domain of Surgery the question of fixed dressings was well set forth by Dr. SOUWERS (Jan. 8th), and that of water dressings by Dr. BOYLAND (Oct. 23d). The prevention of vesical calculus was suggested by Dr. ROSS (Sept. 10th), and the treatment of hydrocele explained by Dr. WIGHT (Dec. 3d). On the specialty of the eye, we have had articles by Dr. SCHELL, who described that peculiar disease, "autumnal conjunctivitis" (Nov. 5th), Dr. LANDESBERG on glaucoma (Feb.

26th), Dr. Oliver, and others: while of articles on aural subjects, we must not fail to refer to the curious observations of Dr. C. S. Turnbull, on the penetration of a lumbricus into the middle ear, and its results (July 9th).

In what relates to Statistical and State Medicine, the first number for the year contained a valuable study of the relation of sex to consumption, by Dr. Sozinskey, bringing forward some entirely new facts in this connection. The hygiene of old age was well set forth by Dr. Vance, (April 16th), and that of infancy, by Dr. Boysen, (October 8th). The two curses of modern society, syphilis and drunkenness, have had ample attention. The lecture of Dr. Fournier, on syphilis in married life (January 22d), can justly be styled startling, and should give all the more weight to Dr. Swayze's suggestions (August 20th), for the protection of the community against this fell destroyer. As to drunkenness, the vivid pictures in Dr. Crothers' studies of inebriety (February 5th, May 7th, September 24th, etc.), Dr. Halloran's paper on dipsomania (March 26th), and Dr. Engel's, on chronic affections of the liver and stomach in drunkards (June 4th), show some of the terrible effects of this widespread vice.

This is but a hasty glance at a small part of the instructive original matter we have laid before our readers. We have not space to refer to the many lectures, hospital reports, and correspondence, that also contain much that is new and useful.

During the year, we have had translated a number of lectures from the most distinguished French and German clinical teachers, and we have reason to believe they have been well liked by most readers. Their themes have been practical, aiming to aid the general practitioner. Thus we may name Weiss on tetany (May 28th), Hardy on cirrhosis of the liver, Bettelheim on tænia (May 7th), Charcot on albuminuria (April 9th), etc. It is our intention to continue these carefully selected translations from time to time.

They have by no means excluded American lectures. Of these we have given a large number, by Drs. Pepper, Goodell, Clark, Mills, Wathen, Bell, etc., besides numerous strictly clinical addresses by the most eminent teachers in all branches.

The department of Special Reports, which we introduced at the beginning of the year, has been steadily maintained, and many readers have expressed their satisfaction at this method of presenting a survey of recent progress in the various specialties of our science. They will be continued as heretofore, and every effort will be made to render them full and accurate.

Such is an incomplete review of the two volumes we have laid before the readers of the Reporter in 1881. We have to thank the profession for its steady support of our endeavors to furnish the best matter in the best shape. It is easy to put out a journal with long reports and numerous extracts; our effort has been to condense and abbreviate. Beyond a certain size, a journal becomes cumbersome and unattractive. Such, now, are several of the English weeklies, and such seems the ambition of some in America. It will not be that of the Reporter.

Notes and Comments.

Mutilation of the Ovary in Situ.

Dr. N. M. Johnson, of Durham, N. C., reports, in the *North Carolina Medical Journal*, the case of a lady, aged thirty-five, who was suffering with severe neuralgia of the right ovary, for which, after all medicinal treatment had failed to give even temporary relief, it was decided to perform ovariotomy. An incision six inches and a half in length was made in the mesian line. Finding the organ firmly adherent to the back; near the upper right side of the sacrum, and fearing to break up so extensive an adhesion, and being further unable to use knife or ligature in so confused a space, it was decided to destroy the vitality of the diseased ovary by mutilating it with thumb and finger nail, which was effectually done and the mutilated organ left in situ. Its size was very little larger than an almond. After this the cavity was cleaned with carbolized spray, intestines replaced, and with needle and well waxed cord about seven sutures were taken through the whole thickness of the wall, including the peritoneum, and between the stitches, if any gaping, a narrow strip of plaster. A soft cotton rag wet in the carbolized water was placed over

the wound, and directed to be changed every thirty minutes.

The next morning the temperature was 101°; pulse 104. Liquid food was ordered to be given *pro re nata;* the carbolic cloths kept strictly up; and thirty drops of laudanum to be given three times daily.

The temperature and pulse rate increased gradually up to the fifth day, when they were, in the morning, temperature 103°, pulse 124; in the evening, temperature 103.5°, pulse 130. Then, with fluctuations, they gradually came down to normal on the eighteenth day.

On the twelfth day the opium was suspended, and an enema of warm water induced a tolerably free evacuation of the bowels.

On the sixteenth day the sutures were removed and the adhesive strips depended on for keeping the wound together, after which there was some little febrile action and pain.

The operation appears in every way to have been a success.

Sulphurous Acid in the Treatment of Diphtheria.

Dr. H. P. Yeomans, of Mount Forest, Ont., states in a communication to the *Canada Lancet*, Dec. 1, 1881, that in the treatment of diphtheria, which has been prevailing to a great extent in that locality since the first outbreak of it in an epidemic form in 1878, he has found a mixture of sulphurous acid and glycerine, equal parts, administered in doses of ten or twenty drops every hour or half hour to be most efficient. In addition to this he gives a solution of tincture of iron and chlorate of potash (to which, in some instances, quinine is added), every three or four hours.

The temperature of the room should be uniformly kept at 80°, and the air rendered moist by evaporating water continuously.

For the complication of croupy symptoms (diptheritic croup), he uses inhalations of carbolic acid and iodine.

He objects to using the brush in applying any remedy to the throat, and regards glycerine as the best article in which to administer sulphurous acid, because it is soothing and forms a protective covering over the tender diseased surface of the throat. When given in ten or twenty drop doses, it retains the sulphurous acid in the fauces, so that its specific effects may be obtained. This mixture frequently repeated and given without any water, is constantly retained, and acts remedially in the throat. As sulphurous acid is very volatile, it penetrates the nasal passages, operating there also quite as efficiently.

On the Indications for the Use of Morphia in Puerperal Eclampsia.

Dr. L. McFarlane, of Toronto, who has found morphia, administered hypodermically, to be a most efficient remedy in the treatment of puerperal convulsions, gives, in the *Canadian Journal of Medical Science*, for December, 1881, his reasons for regarding it as especially indicated in this disease. He first points out what he regards as the true cause of the convulsions, viz., anæmia of the brain, with increased irritability and general exhaustion of the entire nervous system, resulting from the disturbance of the circulation produced by the increased labor required of the heart in carrying on the fœtal circulation. In morphia we have a drug which produces an increased flow of blood to the nerve centres, and by its soporific effect allows the brain to rest while increased power is gained to carry on the nervous functions of the body. The control which morphine exercises over the disease, both in the preliminary stage as well as when the convulsions actually set in, is so prompt and decisive, he says, as to convince the most skeptical after having given it a fair trial. To give any preparation of opium in this disease by the stomach, he regards as of little if any use, as the sickly condition of the organ is such that the medicine is not absorbed in time to be of any benefit to the patient, and moreover, the remedy should be given early and in sufficient quantity (not less than from one-half to a grain) to control the convulsions at once.

Treatment of Wounds from Supposed Rabid Dogs.

No. 16 of the *Progrès Médical*, contains Mr. Durjardin-Beaumetz' conclusions on the above subject:—

1. A person having been bitten by a mad dog, or by one suspected of rabies, the wound must first be made to bleed, then washed, and finally cauterized.

2. All bites, whether trifling or serious, must *immediately* be made to bleed profusely by means of sufficient pressure. They must be washed in plenty of water, or any other liquid, (urine even), until cauterization can be effected.

3. This can be made either with Vienna paste, butter of antimony, chloride of zinc, or a red hot iron, the latter is the best of all, and any piece of iron heated *red hot* will serve the purpose.

4. These cauterizations must reach every part of the wound, and their success depends upon the promptness with which they are applied, Their application can be made by any one before the arrival of the doctor.

5. Cauterizations with ammonia, or with any kind of alcohol are entirely useless.

On the Etiology and Treatment of Tetanus.

In a paper read before the Central Ohio Medical Association, and published in the *Ohio Medical Journal* for December, 1881, Dr. J. H. Pooley, of Columbus, gives the history of a number of cases of tetanus, following various injuries and surgical operations. Nearly all these cases presented this common characteristic, that the wound was bathed in unhealthy discharges, and the Doctor believes the retention of pus in contact with the wound to be one of the most common exciting causes of this disease. He therefore enjoins cleanliness as a prophylactic measure. Under treatment he considers the free incision of wounds, amputation if there be considerable destruction of tissue, and anodyne and antiseptic dressings, for which purpose he gives preference to chloral. General treatment consists in absolute rest, the administration of calabar, which he regards as the remedy *par excellence*, to be given in full doses. Chloral and morphia he considers valuable adjuvants.

Muriate of Ammonia as an Anthelmintic.

Dr. H. L. Getz, of Iowa, writes to us, recommending this product as an anthelmintic. He says:—

"In prescribing it as part of a cough mixture, it was discovered that an anthelmintic effect was produced upon a child which had been taking the cough mixture, and feeling satisfied that if the mixture contained an anthelmintic, it must be the hydrochlorate of ammonia, I, therefore, resolved to test it, and have done so with good results.

Dose for a child five years old, five grains, about .30 gram, in water or syrup, three times a day, before meals.

Hot Water Injections in the Treatment of Dysentery.

Dr. John G. Earnest, of Atlanta, Ga., gives in the *College and Clinical Record*, Nov. 15th, 1881, the history of three cases of dysentery, in all of which copious injections of hot water resulted in almost instantaneous amelioration of all the distressing symptoms, and a speedy cure. This is precisely what we might expect from hot water, the principle involved being identical with that so fully demonstrated by Emmet and others in connection with gynecology.

Beginning with tepid water, the temperature is gradually increased until the limit of toleration is reached. In conjunction with the hot water treatment, the author uses ipecac in full doses (25 to 30 grains) and small doses of morphia hypodermically. From what we know of the action of these remedies, we should say that in their judicious combination we have the best means of combating this often most formidable disease.

Late Effects of Hereditary Syphilis on the Bones.

It is rare that a typical case of hereditary bone lesion from syphilitic disease is presented. Such a one was, however, shown at a late meeting of the Manchester, England, Medical Society, by Dr. Bury. The patient was twenty two. He was quite well till ten years old; then a skin formed over his eyes." He had now symmetrical interstitial keratitis. A little later, his mouth and throat became sore; there was now a hole in the right arch of the palate. At the age of eighteen he noticed that his legs were swollen; the tibiæ were now greatly thickened, and pieces of bone had come away from the right tibia. There was a large gap in the right side of the frontal bone, from which a sequestrum separated a few months since. Two sinuses near the middle of the forehead also led down to dead bone. The lower fourth of the left femur and the back of the right ulna were thickened. The left upper incisor was absent; the edge of the right upper was ground down.

Chronic General Peritonitis.

In the December number of the New York *Medical Journal and Obstetrical Review*, Dr. Alfred L. Carroll records an interesting case of chronic general peritonitis, which seemed to have taken its origin in an old pleurisy on the left side, the inflammation passing through the diaphragm and causing at first a peri-hepatitis, or perhaps an intermediate peri-splenitis. The case exemplifies a condition that has been classed among the curiosities of medical experience, for chronic general peritonitis, independent of tuberculosis or carcinoma, is either ignored or its existence denied by most writers, save as a protraction of an acute purulent attack, and the few who recognize its existence differ as to its pathology and clinical history.

On Chronic Rhinitis.

In a late thesis on this subject, Dr. Gourjon observes that arthritic rhinitis is very rare in infancy, less frequent in adolescence, and common in the adult. It is specially characterized by the presence at the entrance to the nostrils, of pustules very closely resembling those of sycosis or acne. Herpetic rhinitis, independently of the characteristics which are common to it and the other forms of rhinitis, is distinguished by an extreme tenacity and viscosity of the nasal mucus, "whitish and flabby, like a piece of albumen."

The treatment of simple rhinitis should consist in irrigations of the nasal fossæ and the insufflation of astringent powders.

Constitutional rhinitis, while we employ local treatment, demands an active intervention which tends to modify the general condition.

Mercurial Solution for Hypodermic Injections.

M. Yvon has been guided by the theory that a good mercurial solution for injections should not exert any local action, but be absorbed as rapidly as possible. It should, besides, not have the tendency of coagulating albumen.

The following formula gives a liquid realizing those requirements:—

℞. Biniodide of mercury, 1 gram = gr. 15
Iodide of potassium, 1 " = " 15
Tribasic phos. of soda, 2 " = " 30
Distilled water, q.s. for 50 c.c. M.

This solution gives a slight bluish tinge to red litmus paper, and does not coagulate egg albumen. Indeed, when mixed in equal parts with a somewhat concentrated solution of egg albumen, it prevents its coagulation by heat.

Special Reports.

NO. I.—THE MANAGEMENT AND DRESSING OF WOUNDS.

No more generally interesting question in surgery can be named than that of the method of dressing wounds. It presents itself with the occurrence of every lesion, accidental or produced by the interference of the surgeon. There is as yet far from a unanimity on the point, as will be seen by the references which we shall subjoin. Of course, the *antiseptic* method has the most advocates at the present day, and to it we shall give priority.

ECONOMIC RELATIONS OF ANTISEPTIC DRESSINGS.

Prof. Nussbaum, of Munich, in one of his lectures, has some curious observations on these aspects of Lister's discoveries. We quote them from the Edinburgh *Medical Journal*:—

It is certainly easier and cheaper to apply a pad of charpie and some adhesive plaster. The antiseptic dressing which a barber would apply under such circumstances would not, however, cost more than half a mark. Dressings for wounds have become now altogether very complicated and expensive. Formerly cheap adhesive plaster and charpie, which the ladies picked in their leisure hours and gave to the surgeon, were employed, and dressings seldom cost many pence. Now the annual cost of the material for dressings which I employ, exceeds 30,000 marks. There is certainly a great difference between the two. It is also the case that an injury with the treatment of which a surgeon would formerly have been engaged for thirty or forty days, frequently heals up now in five or six days, and the surgeon makes very little out of it. But surgeons can and may state their expenditure, and no medical jurist would refuse to remunerate more highly such speedy and effectual assistance. Furthermore, surgeons do not exist merely for the purpose of making a comfortable income, but that they may render assistance to the sick and wounded, "tuto, cito, et jucunde."

LISTERISM AT HALLE.

In Prof. Volkmann's surgical clinic, at Halle, a strict form of Listerism is used. It is described in a letter to the *Medical Record*, as follows:—

Before operating, the sponges are placed in a 3 per cent. solution, as are the instruments. From time to time the wound is flooded with a 3 per cent. solution, from a small ordinary watering-pot without the sprinkler; and the pot is held high above the wound, so that the stream may fall upon it with considerable force. The catgut and silk used for sutures and ligatures are kept on spools which lie continually in carbolic oil, and the ligatures are cut off and handed to the operator only when required. At the completion of the operation, after the wound has been thoroughly flooded and closed, a hand-spray is used during the application of the dressing. The wound is dressed first with a piece of prepared oil-silk protective, only large enough to cover the wound. Above this is placed a wad of very soft carbolized gauze, which is not folded, but is shaken apart, and made into a soft mass. An abundance of this is used, and then it is covered by an ample piece of gutta-percha protective, reaching far beyond the limits of the wound, and sufficient to render difficult the communication of any discharge with the air. This is held in place with a carbolized gauze bandage. All the interstices are carefully closed with wads of salicylic cotton, the elasticity of which tends to render the dressing more secure; and when complete, the dressing, though seemingly sometimes redundant, fully realizes the object for which it was applied—the occlusion of the wound. When the wounds are opened and dressed, a simple hand spray is used, and the wound is thoroughly rinsed. For this purpose a can filled with a 3 per cent. solution is used, having an opening in its side just at its lower border, to which a rubber tube is attached. This tube has a small nozzle which can be inserted, if necessary, into sinuses. The can is held above the head by an assistant,

and the water thus runs into the wound with considerable force, or by lowering it, with as little force as may be desired. Sponges are used only in the primary operations, and never in dressing wounds; but pledgets of absorbent cotton, which, after being used, are thrown away.

A great difference in the results are claimed in favor of these minute precautions.

THE PRIMARY UNION OF OPERATION WOUNDS.

This is a result naturally much sought after by surgeons. A brief synopsis of the advice of two eminent surgeons, in papers read last August, at London, may be presented.

Mr. SAMPSON GAMGEE believes that the most favorable conditions are gentle manipulation, drainage, dry and infrequent dressing, pressure, and absolute rest, insure the maintenance of accurate apposition of the surfaces and margins of operation wounds, and prevent the effusion and accumulation of fluids within and near the wound. Primary union may be favored by control of the circulation, effected by position, elastic compression, and immobility. Absorbent gauze and cotton dressings are valuable for surface drainage, and, being highly elastic, facilitate soothing, uniform, and safe compression. Antiseptics, always useful in the treatment of wounds, are most called for in conditions where effusion or accumulation of rapidly decomposable products cannot be prevented by position, pressure, or drainage, as in the case of psoas abscess and empyema.

Prof. HUMPHRY defined the principal causes of failure to be the delicacy and sensitiveness of the tissues in infantile and early life, which render them liable to inflammation and ulceration upon slight irritation; the deficiency of the nutritive energy requisite for the healing processes in the atonic and aged; observed most especially in the lower limbs when there is disease of the arteries; and, lastly, the presence of foreign substances in the wound, especially blood or bloody fluid, which separates the surfaces, and has a tendency to decomposition. Accurate apposition of cut surfaces, and prevention of the accumulation of bloody fluid, by non-irritant sutures, rest, gentle pressure, and suitable splints, are the best methods of securing primary union. Effusion of blood after the stitching up of the wound must be prevented by carefully securing the vessels. Dr. Humphrey rather preferred the ligature to torsion, and considered the actual cautery as a useful adjunct. Sponging the wound promotes oozing at the time, and lessens the risk of further exudation. A drainage-tube should be inserted, and blood should be expressed from the wound as long as it continues to flow through the tube after the wound has been stitched up. Antiseptics are considered most valuable under the same circumstances as mentioned by Mr. Gamgee. Esmarch's band appeared to promote bleeding from cut surfaces soon after its removal, but to lessen the risk of further effusion.

INTRA-PERITONEAL WOUNDS OF THE BLADDER.

These extremely dangerous lesions have been experimentally studied by Dr. VINCENT, an abstract of whose investigations we find in the *Medical Times and Gazette*, Oct. 22d. The results may be summed up as follows:—

Immediate union has been obtained in all kinds of wounds of the bladder when the suture has been *immediate*. Treatment (opening the belly, suture of the bladder, removal of urine and extravasated blood from the abdominal cavity, with subsequent suture of the abdominal wall) has been successful, even after six and a half and eight and a half hours after intra-peritoneal extravasation. On the other hand, the operation has constantly proved useless when practiced twenty-four and a half, twenty-five, or twenty-five and a half hours after extravasation, the animals having succumbed to urinary intoxication rather than to the violence of the peritonitis. A vigorous dog may survive an extensive wound of the bladder with intra-peritoneal extravasation of urine and forty-eight hours when left alone. But it is well to bear in mind that in dogs, as in human beings, the susceptibility of the peritoneum differs widely; but even this would not materially affect the final issue.

On the whole, therefore, one may venture to assert that success will belong to the surgeon who operates early; laparotomy must be undertaken early if it is to save the patient. On the other hand, the presence of peritonitis, unless severe, or of uræmic symptoms, does not necessarily render it inadmissible. In civil practice this is not difficult, provided the patieut applies early enough, and that the surgeon arrives promptly at a correct diagnosis; and it may be said that an error in diagnosis, leading to a laparotomy in a case where the bladder, turned out not to be injured, would be less serious than the want of recognition of an extravasation which had taken place. In the former case, the surgeon would at least be able to discover the causes of the symptoms which he believed were due to rupture of the bladder, while, due precautions being taken, the danger to life would be quite insignificant.

Dr. Vincent thinks that our present antiseptic dressings warrant operations which formerly would have savored of almost unpardonable temerity. "*Autre temps—autre chirurgie.*"

DEATH FROM CARBOLIC SPRAY.

Last May, before the Clinical Society of London, A. P. GOULD reported a case of rapid death after antiseptic osteotomy of the tibia, in a lad of eight years, due obviously to the carbolic acid in the spray.

Mr. Gould discussed the question of the production of the fatal illness by carbolic acid. He showed that the vomiting, diarrhœa, nervous symptoms and temperature, were quite in accord with the symptoms undoubtedly produced by carbolic acid, although suppression of urine was a new fact. As nothing was before known of the minute changes in the apparently healthy organs in carbolic intoxication, we had to rely upon the symptoms only for deciding the cause, but it was held that the pathological changes did not contra-indicate the influence of carbolic acid. The quantity of the acid absorbed was probably very small indeed, but children were more susceptible to its influences than were adults. Idiosyncrasy also played an important part in such cases, and there was no evidence of the minimum fatal dose of the acid in man. In conclusion, Mr. Gould maintained that his case was one of carbolic intoxication; and he was led to this view from the absence of other cause of death, and of any facts to negative it; and because the symptoms and *post-mortem* signs, with few exceptions, were those observed in that affection.

The President, who was Prof. Lister himself, agreed in the conclusion as to the cause of death, though he thought it a misfortune the urine had not been examined. The patient happened to be extremely susceptible to carbolic poisoning, like a lady he had treated, in whom the application of carbolic dressing induced vomiting, which ceased on the substitution of boracic dressing.

The case excited a great deal of attention in surgical circles.

SUBSTITUTES FOR THE CARBOLIC SPRAY.

In view of the dangers which attend, in some cases, the use of the carbolic spray, Dr. A. W. M. Robson, of Leeds, calls attention, in the *Brit. Med. Jour.*, October 15th, to some experiments with vapor of oil of eucalyptus and oil of cajuput. These substances also appear to have the power of checking the development of organic life. He writes about them:—

The experiments related go far to prove that, in the vapor of eucalyptus, cajuput, and other similar volatile fluids, we have powerful antiseptics, which, at the ordinary temperature of the atmosphere, may so saturate the air as to kill all infective particles; perhaps, not only bacteria and micrococci, but also the germs of fevers and other infectious diseases.

In a chamber regularly used for operating, there would be no difficulty in having a large pair of bellows, worked by hydraulics, to pump a continuous stream of air, which might be carried to any part of the room by means of a flexible tube; the air having been forced through two or three wash-bottles containing pumice-stone and the volatile oil, cajaput or eucalyptus. If the end of the tube have a large bell shaped opening, the current of air will diffuse itself over a radius of many feet.

He thinks that oil of peppermint, terebene, and other volatile substances would answer as well.

ANTISEPTICS IN OVARIOTOMY.

Dr. Keith and Dr. Bantock, of London, have both renounced the use of the spray in ovariotomy, and returned to the old system, pure and simple, with the best results (*Lancet*, Sept. 24, 1881). The latter observes:—

"If we are to accept the experiments of Mikuliez, the spray must be injurious, inasmuch as he has found that the spray contains four times as many bacteria as the undisturbed air of the room, and that as these bacteria are dry and not in a state to be acted upon by the carbolic acid, they thus gain access to the peritoneal cavity uninjured and ready for their dire work. But we may rest in peace on this account, seeing that the living tissues are able effectively to dispose of them provided they be deprived of appropriate nidus by using a drainage tube."

The drainage-tube is thus a necessity in those cases where the spray is used, whereas it may be dispensed with in many where it is not employed.

THE ANTISEPTIC TREATMENT OF WOUNDS IN WAR.

This was the subject of a paper read before the International Medical Congress, by Surgeon-Major H. F. L. Melladew, M.D. This paper was chiefly founded on the reports made by surgeons who had served in the Russo-Turkish war. The more rigorously antiseptic principles were followed out on the field of battle, at the dressing stations, and at the hospitals, the better were the results. The work of the surgeon was much simplified, for there was no necessity for frequent renewal of the dressings, and more time could be given to the severe cases. The wounded could be more rapidly removed, and were carried to the rear of the battle field, and, if thought advisable, to their homes, in much more favorable conditions than under the ordinary plans. Convalescence was much more rapid. The author quoted the authority of Reyher, Cassimerer, Pirogoff, and other surgeons, in favor of the use of antiseptics in war. Bergmann had successfully treated gunshot fractures of the knee by at once washing the limb with a solution of carbolic acid, then wrapping it in cotton dipped in a solution of salicylic acid (10 per cent.). This cotton was covered in with gutta-percha, and the limb was rendered immovable by plaster-of-Paris. In several of the cases, the wound was found to be healed the first time the dressing was removed. The author insisted on the importance of not at-

tempting to examine the wound by the sound or the finger, and quoted LANGENBECK in support of the principle, which was followed by most of the Russian surgeons in the war. The experience of the Russian surgeons had shown that septic wounds could be rendered aseptic, even though a fortnight had elapsed since their infliction. This had been proved by CAMMERER at Plevna, and by WATRASZEWSKI in the Caucasus. In conclusion, Dr. MELLADEW described a packet of dressing which, he said, every soldier should carry sewn in his coat below the clavicle. He objected to metallic cases, because they might be injured by pressure, and if a ball struck them, they might act as foreign bodies. He recommended a case of linen impregnated with caoutchouc, containing a triangular bandage, a piece of antiseptic lint about eight inches long by three inches wide, and a gauze bandage, one yard long, enclosed in parchment paper. The packet was very cheap, easily prepared, and small.

A SIMPLIFIED ANTISEPTIC DRESSING.

In the *Gaz. Med. de Strasbourg*, 1881, No. 3, E. BOECKEL describes a modification of the antiseptic method of dressing wounds, which he claims to be cheaper, simpler, and more generally practicable than the "Listerian" method. The dressing used is red tarlatan cloth which has been steeped for eight days in a solution composed of

℞.	Carbolic acid,	3 pts.
	Glycerine,	5 "
	Alcohol,	5 "
	Water,	50 "

in a tightly-covered vessel. In urgent cases, as in military practice, one or two hours' steeping might be enough. The cloth is applied wet, and just before being used is dipped into tepid water to get rid of the excess of acid. BOECKEL seeks to obviate the irritating effects of the acid on the skin, and also the risk of carbolic poisoning, by interposing between the skin and the carbolized tissue a layer of tarlatan wetted with plain water. The margin of the dressing is rendered secure against admission of air by strips of wadding, the whole is covered with some impermeable material, and fixed with a firmly applied damp bandage. The impermeable material may be gutta-percha, paper, parchment paper, or oiled paper.

The spray is only used in operations when serous cavities or joints are opened. In other cases, frequent flushing of the wound with antiseptic fluid is considered sufficient.

The author used this in sixty consecutive cases of major operations—*e. g.*, amputations, excision and incision of joints, and laparotomy, and among these were only two deaths, but in both cases the parts were "septic" before operation.

IODOFORM IN UNHEALTHY WOUNDS.

At the Surgical Congress held last spring, in Berlin, a discussion of the value of iodoform in surgery was an interesting feature. In Vienna, especially, the use of iodoform as a dressing of unhealthy wounds has long prevailed, but now it is used somewhat differently, and much more thoroughly. In joint diseases, caries, cold abscesses, etc., the diseased bone, fungous granulations, and other abnormal tissues are removed with knife or curette, the cavity thoroughly washed out with carbolic acid or thymol, and *entirely filled* with iodoform. A usual dressing of gauze and Mackintosh is then applied over all, and the part immobilized by means of an organtine bandage. Unless the discharge soaks through the dressing it is not removed for one, two, or even three weeks. The results obtained have been remarkably good, cases having been cured that would have been amputated under the older methods of treatment. The iodoform diminishes the secretion, prevents its decomposition, and prevents the formation of tubercle in the granulations or destroys them if they are already present. This specific local action on tuberculous granulations has been repeatedly observed, portions of the tissues being examined microscopically before and after its use. This may easily be observed where the granulations have not been first removed.

This observation of the action of iodoform upon tuberculous masses with which it is in contact, led to the trial, in Professor Billroth's clinic, of injecting an ethereal solution of iodoform into joints in the early stages of fungous inflammation, and into other suspected tuberculous swellings. A solution of iodoform in ether, one part to five, is injected with a hypodermic syringe directly into the joint or tumor in several places, one or two syringefuls being used. The ether is immediately absorbed, and the iodoform is left in substance in contact with the diseased tissues.

SPONGE AS A DRESSING.

Dr. JAMES HARDIE, of Manchester, England, called attention to the value of sponge, in a recent article in the *Lancet* (Oct. 15th). He stated that his belief of the proper action of a surgical dressing, was not so much one to absorb discharges, as to render discharges unnecessary. He proceeds:—

For some years past I have been endeavoring to dress wounds with this end in view. I have found that by the use of sponge bandaged over

the surface of the stump or other part, one is often able to secure perfect union of a wound without discharge, and without the need of changing the dressing until the union is complete and sound. Sponge, as you know, is a material which is readily compressible into a very small bulk, and which also possesses a high degree of elasticity or resilience, so that pressure being removed, it immediately resumes its former size and shape. Besides this, its highly absorptive properties, which are commonly taken advantage of in surgical practice, are well known to all of you. For these reasons sponge appeared to be a material well adapted for the purpose I had in view, first and chiefly, to exercise a continuous and elastic pressure, and, secondly, to absorb readily any discharge which might perchance escape from the wound. The sponge I have hitherto mainly employed has been the large-celled honeycomb, and the manner in which I used it is briefly as follows: Antiseptic precautions are used throughout. All bleeding points are carefully closed. Frequent sutures are inserted, so as to bring the edges accurately together. No drainage is used. The sponge, having been soaked in carbolic lotion, is squeezed tightly, to expel every drop of superfluous moisture. The flaps of the stump are meanwhile carefully pressed together by the surgeon, in order to force out any blood which may have collected during previous procedures. And let me urgently draw your attention to this point, since want of thought about it will frequently cause disappointment. Diligently compress the flaps together with your fingers, and so squeeze out every drop of blood; then relax not your hold for an instant, but skillfully place the compressed sponge over the surface, and hold it, and as many more sponges as may be required to cover the entire surface tightly with your fingers, while an assistant secures them in place with a bandage. Sometimes this is rather difficult to do, but by stitching sponges together, some assistance may be gained. The bandage having been applied, you may now cover the whole with antiseptic gauze, or with tenax, with a piece of mackintosh over all; these again are secured with another bandage. In many cases it is advantageous to use as a bandage a piece of elastic webbing. This you may do if you choose.

Especially in smaller wounds he has found this plan most satisfactory.

EUCALYPTOL AS A DRESSING.

During the last summer Mr. LISTER spoke several times favorably of the substitution of eucalyptol for carbolic acid in the spray. A writer in the *British Medical Journal*, gives its pharmacy as follows:—

The substance which we call the oil of eucalyptus is, or was very recently, called eucalyptol by the French chemists. The term is a more convenient one than ours; and, as it corresponds with our other antiseptics—phenol, thymol, etc.—we may accept it, without inquiring too curiously as to its chemical accuracy. The substance, indeed, is only the lighter and more volatile portion of the oil of eucalyptus, which distils over at a temperature below 175° C. (347° Fahr.); a second substance passes over at a temperature of 188° to 190° C. (360° to 374° Fahr.); while a third remains in the retort. On account of the slight solubility in water and its great volatility, Mr. Lister recommends that the eucalyptol should be mixed with damar gum; but it will probably be found that eucalyptus gum—or rather resin—from which the tree derives its popular name in Australia, will be found more suitable. The French have long been employing a combination of the kind, under the name of the *Alcoolature d'Eucalyptus*, a common tincture of the fresh leaves, containing a large amount of the essential oil and resin, some tannin, and probably a little chlorophyll, as it is of a dark olive color.

CREASOTE AS A DRESSING.

This substance was especially recommended by Inspector General MOUAT, member of the Section of Military Surgery at the International Medical Congress. He remarked of creasote that it does not volatilize, and the only objection to it is that it is not easy of solution. But that was easily overcome by using it in a mixture of acetic acid and mucilage, which is readily retained in water; and it retains its powerful odor in all circumstances. About forty years ago, he had occasion to perform an operation in very unusual circumstances. A soldier had been carrying a musket on his shoulder, and the lightning struck the musket and exploded it, twisted the barrel into a coil, and shattered his hand into portions. He amputated the hand with the flap in the usual way. The next day, he saw maggots in the wound. He used creasote to remove them, and had some difficulty in making the solution, until he overcame it as just stated. The result was that the maggots at once disappeared from the wound, which took on a healthy action and healed by first intention in eleven days. Twenty-five years afterwards, the same thing happened in the Crimea, at the assault on the Redan. All the amputations were affected with maggots. He at once applied creasote, and the wounds took on healthy action, and they found subsequently that when a dressing was soaked with this creasote solution, the flies immediately left the dressing.

DRY CARBOLIZED DRESSING.

One of the German speakers at the International Medical Congress, Dr. BECK, proposed the use of dry carbolized cotton wadding for dressings in the antiseptic treatment of wounds, in preference to the spray and wet dressings. He mentioned that this mode of dressing had been used with the best results in the garrison hospital at Carlsruhe (Baden). He described the mode of preparing the carbolized cotton-wool, and the method of using it. He detailed chemical experiments, the results of which had been to prove

that cotton-wadding thus prepared did not lose the carbolic acid with which it was sprinkled in any important quantity for certain periods of time. He alluded to various disadvantages of wet carbolized dressing from which the dry dressing was free. He also referred to objections to dry carbolized tow or jute, from which the cotton-wool dressing was free. He regarded the method he described as being simple, the material cheap, and the dressing one which could be applied easily.

ALCOHOL DRESSING.

Very excellent results in operation wounds are obtained by Prof. ESMARCH with alcohol dressings. He employs pads soaked in absolute alcohol, fixed to the wound by an iodoform bandage. A pillow of jute and gauze is laid over the dressing, and covered by a wet bandage, which is lastly, enveloped in an elastic bandage. His statistics are as follows: In 398 major operations, 85 per cent. of the cases cured healed by first intention, with one dressing; in 15 per cent. the dressing was renewed. There were 146 excisions of large tumors, 40 excisions of mammæ and axillary glands, 14 castrations, with one death from pericarditis and old syphilis, one from apoplexy, one from fatty heart. Of 51 major amputations (thigh 18, leg 27, arm 5, forearm 1), one died from shock and hemorrhage, and one from delirium tremens. There were 61 resections; 11 exarticulations; 26 operations for necrosis; 13 nerve stretchings, one for tetanus, which was fatal; 8 hernias; 21 large cold abscesses; 12 large wounds; 49 compound fractures. Thus the mortality was only 6, or just over 1½ per cent.

SALICYLIC SILK AS A DRESSING.

This substance is highly commended in the *Lancet*, Oct. 8th, by Mr. W. H. BROWN. He says:—

The manner in which I employed the silk is as follows: After having carefully rendered the wound aseptic, according to Mr. Lister's directions, I place over the wound a strip of gauze, soaked in a five per cent. solution of carbolic acid; then surrounded the wound with a double handful of salicylic silk; over this I put the gauze and mackintosh pad, and bandage in the ordinary way. It is a most important point to have the silk thoroughly teased out; in my earlier cases I was not successful, owing, I believe to the fact that I used the silk in masses. One handful of the material, as sent out in parcels, should yield about four times that quantity after being teased. Another point is to bear in mind that salicylic silk has not power to render aseptic an already putrid wound; so long as the discharges are sweet, so long will the silk maintain them aseptic; but if the discharge be putrid, no amount of silk dressing will render them sweet.

He gives a tabular view of the result of a number of cases treated in this manner, including amputations, resections, etc., which show strongly in its favor.

(*To be continued.*)

CORRESPONDENCE.

Susceptibility to Variola.

ED. MED. AND SURG. REPORTER:—

In your issue of Dec. 3d, I notice some points raised by Dr. Helm, regarding the susceptibility of a certain class to variolous poison; one of his points has been the subject of some study on my part, and hoping to gain the opinion of older and more experienced men, I am led to give a few of my observations. I refer to his third question. I find among the laity an almost universal opinion, and, indeed, among some physicians, that an attack of any of the zymotic diseases in the pregnant female will exempt the child from future attack. But from my own experience, and others which I have seen, I am led to the conclusion that if such is the rule, the exceptions to it are so numerous that but little dependence can be placed upon it as a prophylactic means. Of the considerable number of cases I have collected I will cite but three.

CASE 1.—Mrs. N., primipara, aged 27, was attacked with anginose variety of scarlatina, about the eighth month. About five days after the onset of the fever she was delivered of a pretty large boy, presenting a characteristic rash all over his chest, neck and face; this subsided and disappeared in about two days, the child showing no further symptoms, but died in its third year, of the same disease in the malignant form.

CASE 2.—Mrs. R., during her second pregnancy, was attacked with the measles—this was during the fourth month. She went to her full term, the child showing no evidences of the malady, but it subsequently did have a well defined case of the same disease.

CASE 3.—Mrs. P. was vaccinated during her first pregnancy, and so violently did the virus attack her that she was confined to her bed for two weeks; the scars (two in number) are as large as a silver half dollar. The child was recently vaccinated by myself, and it worked very successfully, a well marked scar showing in each place.

Such cases as these, and others that have come to my notice, convince me that little dependence can be placed in the fact that the pregnant female has had a contagious disease, or that she has been vaccinated while in this condition. I believe that in every person who has a contagious disease there is a special affinity for the poison of that particular disease, and that this affinity is an abnormal condition, a disease, so to speak, the conditions necessary to the existence of which we are at present in ignorance of, and hence we cannot say whether or not it may exist more than once. I believe that an attack of the disease exhausts this affinity and thus renders the subject exempt till the condition re-exists. Believing this, it is easy for me to see why many cases occur where the child fails to be exempt, even where the mother has been attacked while it was a fœtus in utero.

Colfax, Iowa. FRANK PORTERFIELD, M.D.

A Case of Precocious Development.

Ed. Med. and Surg. Reporter:—

On the 5th of October, 1881, I was called, in consultation, to see two children having typhoid fever; the elder a boy of twelve, the younger a girl of eight in March last. Having learned the age of this little girl. I was every now and again struck with something in her appearance and behavior incompatible with her age. Her limbs appeared stouter, the expression of the face partly that of the child, and partly that of a woman; a curious, undefinable mixture of the two. I also noticed the same curious blending of the woman and the child in the mind and nervous system. I saw her again a few days later, when I was more than ever struck with the womanliness of this little girl.

All this was explained to me, when her father communicated to me the fact that she had already menstruated twice; the second time just before the onset of fever.

I communicate this case as one of sufficient interest to challenge attention, on account of the very unusual precocity of the menstrual function, as well as of physical and mental development accompanying. This little girl has made a recovery from the attack of fever, and I shall take an interest in her future history.

T. M. Harris, M.D.

Harrisville, W. Va., Dec. 27th, 1881.

Carbolic Acid as an External Application to Piles.

Ed. Med. and Surg. Reporter:—

On November 28th, 1881, Mrs. J. L. B., aged 34, gave birth to her third child, a large boy. There was nothing unusual in her labor, except that the second stage was prolonged by the cord being encircled three times around the neck of the child. When the head was born, in order to prevent asphyxia of the child, and to give complete birth to it, after attempting to unwind the cord from the neck of the child, but failing, I concluded to cut the cord. Mrs. B. did well till December 8th, when she was attacked with metritis accompanied with excessive diarrhœa. On December 11th her temperature arose to 105° and pulse to 140, and she became very delirious. I injected into the vagina, every three hours, a solution of hot water and carbolic acid, ʒj to the pint; warm poultices of flaxseed meal over the abdomen, and a teaspoonful of the solution of sulphate of morphia every six hours, and withdrew her urine by silver catheter. She finally recovered and was able to sit up on December 21st.

Mrs. B., during the last three months of her pregnancy, suffered severely with external and internal hemorrhoids. She stated that she suffered about the same length of time in her other pregnancies, and also for six months after the birth of each of her first two children. I discovered upon examination after she had been attacked with metritis, that there were about a dozen hemorrhoids around the anus, some as large as a walnut, others smaller, which were very much inflamed and irritable. I had a knowledge of the fact that a strong solution of carbolic acid injected into a pile was stated to be a specific plan of treatment. It is claimed that the remedy acts in effecting the cure by coagulating the blood in the pile or piles so acted upon; but it is not certain that carbolic acid does effect the cure in this way. Reasoning from the above premises, I thought the same effect might be produced by the absorption of carbolic acid. I therefore, when her convalescence from metritis was established, determined to bathe the projecting piles with a warm solution of carbolic acid $\frac{1}{30}$ and also to inject into the rectum, for the internal piles, a warm solution of carbolic acid, ʒj–Oj. In two or three days the inflammation, irritation and pain of the external hemorrhoids subsided, and the piles contracted, and at my writing, December 27th, she is perfectly well of both external and internal piles. I merely suggest that the absorption of carbolic acid, either by ointment or solution, may have, as I believe it had in the case of Mrs. B., a beneficial influence in the cure of piles. I hope some of my professional brethren will make further trial as to the efficacy of this remedy in the cure of piles by absorption. J. M. Batten, M.D.

News and Miscellany.

Antagonism of Typhoid and Intermittent Fevers.

Dr. Edwin M. Snow says, in his last report as Health Officer of Providence, R. I.—

There was only one death in Providence from typhoid fever in the month of November; the annual average in November, during the ten years previous, was nearly nine. During the ten years previous to the present, in the four months, August to November inclusive, there was a total of 298 deaths from typhoid fever in Providence, or an average of 29.8 in each year. During the same four months of the present year, there have been only ten deaths from this disease. We are not prepared to explain this difference. It has been said that intermittent fever and typhoid fever are, to some extent, antagonistic, and that when fever and ague is present, typhoid fever disappears. This needs confirmation; but there has been much fever and ague in Providence this fall, with a very great decrease of typhoid fever, while in Boston, during the present autumn, there has been a very great amount of typhoid fever, and very little, if any, intermittent fever.

Dispensary for Diseases of the Ear.

The Trustees of the Presbyterian Hospital in this city have authorized the formation of a Dispensary service for diseases of the ear, to be held every Monday, Wednesday, and Friday afternoons, from four to five o'clock. This service will be in charge of Dr. C. H. Burnett, the aurist of the Hospital.

Items.

—The yellow fever epidemic on the island of Barbadoes baffles the skill of the authorities. No sooner is the disease subdued in one district than it reappears in another.

—A Pay Hospital for women in moderate circumstances has been organized at Atlantic City. Particulars can be learned from Dr. W. H. Bennett, 332 South Fifteenth street, Philadelphia.

—Dr. Thomas W. Grimes, aged about sixty years, and a prominent physician of Columbus, Ga., died suddenly, while sitting in a chair, December 12th. Heart disease is assigned as the cause.

—A German in Chicago, aged fifty-five, was bitten by a Spitz dog seven weeks before, and died of hydrophobia at his residence in that city, December 18th. It is alleged that this breed of dogs is peculiarly subject to hydrophobia, and hence especially dangerous as pets.

—Mental Pathology: "Don't you think," asked Brown, "that Pingrey is laboring under a hallucination?" "No, I don't," replied Fogg; "he has a hallucination, but I don't believe he is laboring under it. I never knew him to labor under anything."—*Boston Transcript.*

—A family of seven persons, named Lacy, have been badly poisoned in Bloomington, Ill., by eating canned fruit. In such cases the accident is usually attributed to some of the poisonous salts of tin derived from the action of the vegetable acids on the metal of the can. The condition of the fruit itself may have been at fault.

—The *Pekin Gazette* publishes a decree of the Emperor Ouang-su, announcing that the second reigning Empress, who had been ill for some weeks, has recovered her health and resumed the direction of the affairs of the State. The same decree confers a whole crowd of honorary distinctions, such as peacock feathers, red and blue buttons, etc., on the members of the college of physicians of the court, twenty-four in number, who daily visited the august patient and felt her pulse, one after the other.

—An exchange has the following just comment on a recent sanitary lecture: "Dr. Pulte, speaking of smallpox, says, 'the pustules first appear on the face, then on the breast, and lastly on the extremities. Thus, a wise Providence has divided the burden into three parts, which would otherwise be unbearable.' Wouldn't it have been a good plan to divide it still more, so as to make it harmless? Even with the present wise arrangement it proves 'unbearable' in many cases. If Dr. Pulte is not ashamed of such puerile reasoning, then he ought to be."

OBITUARY NOTICES.

JAMES M. SHEARER, M.D.

Doctor Shearer died at his residence in Dillsburg, York county, Pa., on the morning of December 14th. He was graduated from Dickerson College, Carlisle, in 1853, and a graduate of the Pennsylvania Medical College in 1858, and immediately thereafter began the practice of medicine in Dillsburg, in connection with his father, the late Dr. Geo. L. Shearer. Soon after the outbreak of the late civil war, the Doctor entered the service of the United States, serving in the capacity of Assistant Surgeon and Surgeon, with credit, in the various field and hospital duties to which he was assigned. In 1866 he returned to Dillsburg, and again resumed the practice of medicine, in which he was actively and successfully engaged until about two years ago, when he was attacked with the illness which terminated his life.

Dr. Shearer was a man of more than ordinary attainments, and of a genial and generous character. Resolutions of respect to his memory and of sympathy with his family, were passed by the York County Medical Society and have been received by this journal.

PROFESSOR PIROGOFF.

The death of Dr. Nikolaus Pirogoff is announced from St. Petersburg. He was Professor of Surgery to the Medico-Chirurgical Academy in St. Petersburg, and a member of the consulting staff of several hospitals in that city. In 1840, he brought out a valuable treatise on the division of the tendo-Achillis in orthopædic surgery. He also wrote on cholera, on the surgery of the arterial trunks and of fasciæ, and on the medical aspects of the Caucasus, and on topographical anatomy. His work on this last subject forms a fine atlas of anatomy, as illustrated by frozen sections. It is with military surgery that his name will ever be most closely associated. He is the medical historian of the Crimean and Circassian campaigns; and also wrote a report on the permanent and improvised military hospitals in Germany and Alsace-Lorraine during the war of 1870. The late Professor is best known in this country from the operation named for him.

DR. BRIQUET.

Within a month of the death of Professor Bouillaud, the Nestor of the Academy of Medicine, the other Nestor, Dr. Pierre Briquet, has passed away at the same age—eighty-six. They resembled each other in their constant attendance at the meetings of that learned body. Indeed, of Dr. Briquet, it has been declared that he never missed a meeting since his nomination in 1860. Like Bouillaud, too, shortly before his death he read a memoir, being a kind of supplementary chapter ("Prédisposition á l'Hystérie") to his well-known work on hysteria. He was for a long period Physician to La Charité, and wrote on cholera and many other medical topics.

QUERIES AND REPLIES.

Pumpkin Seed.

Dr. N. L. F., of New Hampshire, writes: "Will some reader give the chemical ingredients and medical properties of the pumpkin seed? Is it narcotic?"

Antiseptic Treatment.

Dr. D. S. B., of Pa., asks: "Whether the antiseptic treatment was originated by a French surgeon or by Lister? The claim to its discovery has been made by more than one Parisian surgeon, but that peculiar plan called *Listerism*, is undoubtedly a device of the surgeon from whom it is named. It was introduced into France chiefly by Lucas-Championniere, and Prof. Fonssagrives, who is never behindhand in preferring the just claims of his compatriots, unqualifiedly attributes it to the Scotch surgeon. (See his *Traité de Therapeutique*, vol. II, p. 176).

Lecture.

MEMBRANOUS CROUP AND LARYNGEAL DIPHTHERIA.

Delivered at the Medico-Chirurgical College, Philadelphia,

BY HUGO ENGEL, A.M., M.D.,

Professor of the Principles and Practice of Medicine and of Clinical Medicine, etc., etc.

Gentlemen:—It is really remarkable that, notwithstanding many eminent authorities have proven, over and over again, that membranous croup and laryngeal diphtheria are two totally different diseases, utterly distinct from each other, there are still many physicians who believe in the identity of the two maladies. Only a week ago, one of our oldest medical journals,* enjoying a very large circulation, published a communication intended to show that the two diseases are one and the same. Regarding treatment, and especially prophylaxis, however, it is of the greatest importance to distinguish between both maladies, and I shall endeavor, in the following, to point out to you the differences existing between them, and I hope to be able to convince you that they are not identical affections.

What is membranous croup, how does it begin, what is its cause, its pathology? First, it is a disease met with in childhood only. The child, after having been exposed to a cold draught, or after having taken cold in some other manner, goes to bed well and apparently in perfect health. About midnight it suddenly awakes with a hoarse cough, sounding like the barking of a dog, with difficulty of breathing, a hoarse voice, high fever and a rapid pulse. After a few such seizures the child falls asleep again, but the fever continues. The next day the child's voice is still hoarse, it still has fever and some dyspnœa, and occasionally the "croupy" cough, but it plays, and excepting the affection of the larynx and the symptoms mentioned, nothing seems to ail it. When you now look at the parts at the back of the buccal cavity, the tonsil, soft palate and pharynx, you may find them a little red, but nothing more. If you have an opportunity of inspecting the larynx, you will see its whole mucous membrane inflamed and swollen, especially that of the true vocal cords. The next night the child becomes decidedly worse. The spasmodic seizures of coughing and of alarming dyspnœa appear more and more frequently, the voice or cry gets hoarser, and the difficulty in breathing greater and more continuous, while the fever does not abate. Inspecting now the pharynx and neighboring parts, you see nothing more than at first, but in the larynx you observe a grayish-white membrane lining the infiltrated and inflamed mucous and submucous tissues. The child is still strong, fighting, as it were, against the disease, and may now get well if, by vomiting, the false membranes are expectorated, and no new formation of them takes place. In such a case, the voice gradually regains its clear sound, the cough becomes moist and loses its barking character, the difficulty in respiration and the fever leave, and within a day or two the child is *totally* well, never under any circumstances suffering from any sequelæ whatever. But if the case takes an unfavorable turn, the voice soon becomes whispering, the cough spells gradually cease, the dyspnœa changes into apnœa, and the at first bluish, later pale appearance of the

* Medical and Surgical Reporter, December 3d, 1881, page 631.

face, with its expression of terror; the blue lips and the pitiful, but fruitless endeavor of the poor sufferer, to inhale air; the longing of the system for oxygen, precede the terrible closure of the sad scene—the fearful struggle for life—the death by suffocation. Happily death soon sets in; poisoning of the blood from accumulation of carbonic acid, or rather from want of oxygen in the blood, produces early total insensibility, so that the suffering is felt less by the doomed child, which dies in coma. During the last twenty-four or thirty-six hours you may observe, when then examining the throat, an extension of the false membrane, from the larynx upward into the pharynx. And you will further notice, that the child's strength commences to give away then only, when the repeated attacks of vomiting, or at last the want of oxygen in the system, have undermined its vitality. Towards the end of the malady, when death is near, you will detect albumen in the urine, not, however, till the dyspnœa has become greater and constant. (A similar albuminuria is met with in all diseases in which great difficulty of breathing forms one of the main symptoms, as, for instance, in pneumonia, in asthmatic seizures, etc.) But there is no enlargement of glands, and no complication whatever makes its appearance.

In some cases, especially in somewhat older children, of about four or five years of age, the beginning of the disease is sometimes in so far slightly different, as a common bronchial catarrh may, for a few days, precede the outbreak of membranous croup; otherwise the course of the malady is as described.

Let me now, gentlemen, draw before your mental eyes a picture of an attack of laryngeal diphtheria, and for the sake of better comparison, as we see it in children, though adults also may be affected by it. At first you will find that diphtheria is either endemic or epidemic at the place, or you have the fetid odor of badly smelling water closets pervading the house, or the child had been visiting, within the week preceding its illness, a locality where the contagion existed. The first symptoms the little patient generally gives of being sick are: the child loses its appetite, has a moderate fever, and complains of pain when swallowing. It ceases playing almost from the very beginning, drops its head, and shows other signs of weakness by complaining of feeling tired, by not wanting to walk and preferring to lie down. If you now examine the child you will find, on each side, the glands under the angle of the lower jaw swollen, generally on one side much more than on the other, and on inspecting the parts you will notice a patch of false membrane over one or both tonsils, or over a part of the posterior wall of the pharynx, or over the soft palate, extending sometimes along the roof of the mouth. The child has an utter disgust for food, there is a bad odor of the breath, a moderate fever, and a remarkable weakness. If the glands are enlarged on one side specially, you will observe the deposit of false membrane on that side of the throat. On removal of the membrane, you will see below it the healthy mucosa. After the child has been ailing this way from three to five days, getting weaker from day to day, and beginning, perhaps, already to show evidences of septicæmia, it commences to cough. This may happen any time of the day or night, mostly toward morning. The cough has a croupy sound, and the voice becomes hoarse. If you now look at the throat and the larynx you will observe that the false membranes have extended from the tonsils or pharynx down over the epiglottis into the larynx. From the moment of the further extension of the false membranes—they may now spread upward over the posterior nares, or downward into the larynx—you will detect, on examining the urine, that it contains albumen, as it does in every grave case of diphtheria. The albumen does not wait with its appearance till great dyspnœa sets in, as is the case in membranous croup, but is present from the moment the diphtheria takes on a grave aspect. The case of the child with laryngeal diphtheria progresses now, as far as laryngeal symptoms are concerned, the same way as membranous croup, only you can notice the child fighting less against the disease; it gets weaker and weaker, and you observe, clearly, that there is another factor evidently, besides the threatening suffocation, producing the fatal end, and that is blood poisoning. And it frequently happens that the child dies at the very onset of the laryngeal symptoms, death often taking place long before the accumulation of false membranes had been sufficient to induce death by closure of the glottis, by suffocation. Sometimes endocarditis sets in, hastening the fatal end, or what also never is observed in membranous croup, the membranes extend upward over the Schneiderian mucous membrane of the nose. In case the child gets well, the symptoms do not rapidly cease with the expulsion of the membranes from the larynx. No, the child only very gradually regains its strength, and convalescence lasts at least two weeks or longer. Frequently, some days after the disease is apparently over, the mother suddenly observes that the child, when drinking

water, cannot swallow, and that the fluid returns by the nose again; paralysis of the soft palate has set in, and this is always followed by other local, or by general paralysis, sequelæ which never appear in membranous croup.

From the description I have given you of the two diseases, you will have observed that the following differential points clearly distinguish membranous croup from laryngeal diphtheria. For their better contrast, I have written this table on the blackboard, showing the differences mentioned:—

Membranous Croup.	*Laryngeal Diphtheria.*
Is due to exposure to cold.	Due to a specific poison.
No period of incubation.	Period of incubation 1 to 5 days.
Is a local disease, consisting of an inflammation of the mucous membrane of the larynx with exudation of false membranes.	Is a constitutional disease, where bacteriæ are deposited and form false membranes on the mucous membrane of the larynx.
The false membranes, beginning in the larynx, may extend from there to the pharynx.	The false membranes exist at the beginning of the disease in the pharynx, and extend from there down to the larynx, and frequently up into the nose.
Affects children only.	Attacks adults also.
Begins mostly suddenly, at midnight, with croupy cough, etc.	The child has been ailing 3 to 5 days before croupy symptoms appear.
The child loses its strength only after frequent vomiting and towards close of the disease.	The child becomes weak from the very beginning, and loses strength rapidly, even before appearance of croupy symptoms.
Never any constitutional symptoms except high fever (symptomatic of the violent larynx inflammation) and near death, symptoms due to want of oxygen.	Constitutional symptoms from very beginning, moderate fever long before laryngeal symptoms, and child dies often from septicæmia before death by suffocation sets in.
Never any complications.	Often nasal diphtheria, sometimes endocarditis, always septicæmia.
Albumen in the urine only after dyspnœa has become great.	Albumen in the urine from the very beginning of graver symptoms.
Never enlargement of glands.	Enlargement of glands from very beginning, and never absent.
Never contagious.	Very contagious.
Never followed by any sequelæ.	Frequently followed by local and general paralysis.
Rapid convalescence.	Very slow and tedious convalescence.
False membranes soluble in potash solution, hardening in sulphuric acid.	False membranes soluble in sulphuric acid, hardening in potash solution.
Membranes consisting of new formation of cells.	Membranes consisting of masses of bacteriæ and cells.

Gentlemen, these differences are not the result of artificial work, but they appear in every case of either disease, and are taken from nature; and I hope that I have convinced you that membranous croup and laryngeal diphtheria are by no means identical, but totally different diseases, distinct from each other. And let me impress upon you once more the fact, that while the former is a local, the latter is a constitutional, infectious, contagious disease.

Communications.

THE RATIONAL TREATMENT OF BLENNORRHŒA.

BY GEORGE H. PICARD, A.M., M.D.,
Of Topeka, Kansas.

In those cases of long continued and persistent gleet occurring as sequences of blennorrhagia, or any other acute urethral irritation, depending upon a structural alteration of some portion of the urethral lining, the surgeon is not unfrequently humbled; indeed, it is proper that a certain degree of humility should attend the undertaking of one of these cases, which has most likely been a *bête noir* to many an unsuccessful *confrère*.

The pathology of the disorder is confessedly obscure. Some radical surgeons teach that every gleet depends upon a stricture more or less developed; it may be so slight as to have escaped observation. Such gleets are undoubtedly common enough, as is shown by their gradual disappearance during dilatation. It will be found, however, that a large proportion of gleets do not yield to dilatation or mechanical compression. In these muculent fluxes there seems to exist a condition analogous to the chronic and passive congestion of the gynecological phenomenon known as hyperplasia. The lesion, which consists essentially of structural change, is situated in the prostatic urethra, and if undisturbed, is likely to involve the prostate gland and even the vesiculæ seminales.

For my part, I confess that I am unable to differentiate—without historical aid—between the fluxes which accompany the hyperæsthetic state of the urethral lining in masturbation and excessive venery, and the phenomenon known

as ordinary gleet. The microscopic appearance is identical, excepting, perhaps, a greater evidence of ulceration in the gleety discharge; in advanced gleet there is the same presence of scaly epithelium and prostatic cylinders, showing hypersecretion of the glandular surface.

It seems to me that there exists no important difference in the etiology of these fluxes; the chronic discharge of blennorrhœa is caused by the injury done the mucous membrane by the intense irritation of blennorrhagia, rather than any specific violence inflicted by the virus; the fluxes of masturbation and imaginary spermatorrhœa are the result of habitual genital excitement.

If the pathology of these phenomena is identical, it would follow that the same treatment would be successful in both forms. This conclusion would be rational were it not for the fact that in masturbation the continuation of the habit affords a constant supply of fresh irritation, a condition which obviously does not obtain in blennorrhœa. If, then, the surgeon could be assured of the absolute reform of his patient, he might proceed accordingly.

I believe that more cases of obstinate and long-continued gleet have been cured by Lallemand's method than by any other means; yet the procedure is a severe one and by no means devoid of hazard. There is no especial use in disguising the fact that modern conservative surgery looks unkindly upon the employment of the caustic.

Some months ago, in consequence of the satisfactory results I had already obtained from the use of hot water urethral irrigation, both in prostatorrhœa and passive seminal fluxes, and also influenced by the pathological analogy existing between these disorders and blennorrhœa, I determined to employ the thermic agency in the treatment of the latter. Thus far my success has been very gratifying. *In no instance has the scheme failed to yield a radical cure.*

The plan I pursue is simplicity itself, and may be briefly described as follows: A small-sized, bulb-tipped catheter, having lateral openings, is to be inserted into the portable urethra, so that the bulbous extremity will occlude the mouth of the bladder; the free extremity of the catheter is to be connected with a rubber tube which is attached to the faucet of an elevated vessel containing the water; the water is thus, by the force of gravity, thrown into the urethra, and after being distributed over the desired surface, finds a ready egress through the ample space left in the urethra by the small catheter. No fears need be entertained that any injury will be done to the bladder; it is not likely that any water will pass the close-fitting bulb, certainly not sufficient to light up any inflammation.

To insure complete success, this treatment demands the strict observance of the same conditions that are laid down in vaginal irrigation—perseverance, frequency and conscientious regard for details. I begin with water at a temperature of 90° F., which I increase as rapidly as tolerance can be established, to 100 or even 115° F. At least two sittings of fifteen minutes each should be daily required of the patient. The temperature of the water should be maintained by frequent additions from a vessel of boiling water. If any more active stimulation is desired than is afforded by the hot water alone, or if an increased sedative or alterative action seems necessary, it may easily be obtained by medicating the water. I have found the hot water sufficiently alterative.

It may seem presumptuous for me to call this a *rational* treatment, when it is remembered that so little is yet really known of the pathology of these lesions; but I trust that I may at least seem less empirical than the advocates of nauseous anti-blennorhœtics.

In conclusion, I will add a brief record of three cases recently cured by this method:—

Case 1.—W. T., American, aged 21, first contracted blennorrhagia two years ago. I treated him for an acute orchitic testicle, and afterwards for a muculent discharge, which, in spite of my best efforts and a complete exhaustion of the conventional medical and surgical resources, persisted until six weeks ago. At last, being thoroughly disgusted with the non-efficacy of tonics, stimulants, sounding, etc., I began the hot water treatment. After two weeks the discharge disappeared, and has not returned, although four weeks have elapsed. A remarkable feature of this case is the constancy exhibited by the patient; it is easily accounted for when I confess that for three-fourths of the time he was an inmate of a charitable institution of which I have the medical charge.

Case 2.—P. M., Irish, aged 25, first contracted blennorrhagia and chancroid eighteen months ago. In due time the chancroid healed, but the flux continued. Has had the services of seven physicians during the past year, without perceptible change in the gleet. After two weeks of the hot water treatment the discharge ceased, and has not returned after four weeks.

Case 3.—T. T., American, aged 16. In spite of the tender age of this patient, he contracted blennorrhagia nearly two years ago. On account

of excessive shame, he had no treatment for the acute period, but suffered in silence until he began to be alarmed at the long duration of the discharge. I employed the hot water treatment for three weeks, and there has been no sign of a return of the difficulty for two months.

In all of these cases I used, as an adjunct, the hip bath, as hot as could be borne, but no medicine of any kind. In two other cases in which I also resorted to urethral irrigation, with perfect success, I prescribed minute doses of atropia.

SOME POINTS IN REGARD TO TROPHIC NERVE CELLS.

BY J. S. WIGHT, M.D.,

Professor of Surgery at the Long Island College Hospital.

Written for the MEDICAL AND SURGICAL REPORTER.

It is a fact of primary importance, that some nerve cells and muscle cells are co-related. If the muscle cells, from any cause, have no nerve cells to act on them, they will atrophy and degenerate; and if the nerve cells, from any cause, have no muscle cells to act on, they will *probably*, in time, atrophy and degenerate. These remarks are made in regard to the motor nerve cells connected by nerves with both voluntary and involuntary muscle cells. So that if we impair the function of the nerve centre of a muscle, we impair the function of that muscle; and if we impair the function of a muscle, we in a certain sense impair the function of its nerve centre. Of course, an impaired muscle, as well as an impaired nerve centre, may be repaired—to a limited extent—entirely, or not at all. The co-relation spoken of may be more regarded in the light of anat my than physiology. But physiologically and physically, however, there is a *cor-relation* of *energy*. And there can be no doubt that the avenue of correlation is the axis-cylinder. The molecular activity of the nerve cell acts on the molecular structure of the muscle cell, and the molecular activity of the muscle cell reacts on the molecular structure of the nerve cell. The energy of the nerve cell that is transmitted along the axis-cylinder is correlated into part of the energy of the muscle cell—perhaps a very small part—and the resultant coming from the combination of nerve work and muscle work, being muscular contraction and the expression of neuro-muscular work; and the energy of the muscle that *reacts* along the axis cylinder is, as it were, correlated into a certain part of the special energy of the nerve cell, the resultant coming from the combination of muscle work and nerve work, and what we call nerve function, being really the expression of musculo-nerve work. There are two factors, and they coöperate. Instead of motion being accomplished by means of one cell, it is accomplished by the coöperation of two cells. There is, so to speak, a division of labor, a differentiation of work, and while it is admitted that the nerve cell communicates motion, a kind of liberating motion, to the muscle cell, it does not seem so clear that the muscle cell communicates any motion to nerve cell, and yet the conclusion must be reached that the muscle cell *reacts* on the nerve cell, so that there is a most intimate dynamic relation between these cells, that is, the nerve cell and the muscle cell,

This assumption is, as it were, based on the well known law of mechanics, that action and reaction are equal; and if there be no reaction of a molecular kind in the case under consideration, there is still an opportunity for such a reaction, and what is more to the point, perhaps, if the nerve cell has no muscle cell to act, its legitimate action and discharge of work cannot take place.

The health and integrity of the muscle cell, and so far its nutrition, depend on the health and integrity of the *motor* nerve cell; and the health and integrity of the *motor* nerve cell, and so far its nutrition, depend finally on the health and integrity of the muscle cell. The molecular activity of the muscle cell is thus related to the health and integrity of the nerve cell, and the molecular activity of the motor nerve cell is thus related to the health and integrity of the muscle cell.

Now, is it not true, that the muscle cell is a special—a *differentiated*—cell? Say, in a sense somewhat analogous to the fact that the liver cell is a special—a highly differentiated—cell. And can the statement be contradicted, that the liver cell is co-related to the nerve cell, and that the molecular activity of the liver cell and the nerve cell are *cor-related*? I think we need not be detained on this point. But we may add, that the special function of the liver cell and the nutrition of the liver cell are so intimately related, that they must go on together. Hence, to disturb the nerve cell, that is co-related and cor-related to the liver cell, is to disturb, not only the function, but the nutrition of the liver cell. On the other hand, to disturb the nutrition and function of the liver cell, will disturb the function and the nutrition of the co-related and correlated nerve cell. Do not diseases of the liver cause hypochondria? Do not some kinds of mental emotion cause disturbed conditions of the liver? But the liver is not

an organ for making muscular motion—it is an organ where the motions of nutrition take place. It is an organ where molecular motions do not eventuate in molar motion. Nevertheless, it is an organ that is co-related and correlated to the nervous system. Again, there are two factors, and they coöperate. The function of the liver cell is the resultant of a combination of transmitted nerve action and a certain quantum of associated liver action. The liver is a consociated and a dependent organ, having a copartnership with the nervous system; especially the ganglionic system. And if the ganglionic system had no work to perform, it would, in time, atrophy and degenerate.

If we are permitted to reason by comparing facts, and by analogy, we must come to the conclusion that other specialized cells of the body are also co-related and correlated to the nerve cells. Take, for instance, the cells of the connective tissue in various parts of the body. The connective work and the frame work performed by these cells is to some extent correlated with the nerve work of some of the nerve cells. Why should a muscle cell and a liver cell be connected dynamically with the nerve cells? And why should the connective tissue cells be cut off from any dynamic relation with nerve cells? There is no reason why in nature this should be so. There is no reason why the principle of differentiation for special work should not hold good for a dynamic relation between a connective tissue cell a nerve cell, as well as between a muscle cell and a nerve cell, and as well as between a liver cell and a nerve cell.

To be sure, the relation between a muscle cell and a nerve cell is more apparent than the relation between a liver cell and a nerve cell, and far more apparent than the relation between a connective tissue cell and a nerve cell, simply because molar motion is more tangible than molecular motion. Yet, I think the facts of nutrition as involved in molecular activities, and as dependent on the influence of nerve cells, may with some degree of success be elucidated and illustrated. I think it may be somewhat conclusively shown, that the nutrition of various parts of the body depends more or less on some of the nerve cells.

It is not to be supposed that every cell, other than a nerve cell, is directly connected with a nerve cell: It may, however, be supposed that groups of special cells are connected with special nerve cells; for instance, a nerve cell is dynamically related to a group, more or less extensive, of special cells, such as muscle cells, liver cells, or connective tissue cells. The small mass of the central part of the nervous system is in favor of this supposition. Suppose, to illustrate, we had an army with a general to every private; what would it be good for? Too many generals would be as bad as none at all; but subordinate commanders, having a group of men under each, would be useful: And this seems to be to some extent the practical relation of the nerve cells to the other special cells of the body.

As if to strengthen this view, it would appear as if the ganglion of the posterior spinal nerve root were an aggregation of nerve cells, and that these nerve cells are in co-relation, and in correlation with the ectodermic cells. At any rate the integrity of the ectodermic cells is connected with the integrity of the ganglion cells, and the integrity of the ganglion cells bears some relation, perhaps, to the integrity of the ectodermic cells to which they are anatomically related; and more than this, the sensory impressions must pass through these cells on the posterior spinal roots; and this shows that the nerve cells proper have the power of conducting impressions, and it also shows, that the function of conductivity is *complemental* to the normal nutrition of the nerve elements, just as the function of contraction is *complemental* to the normal nutrition of muscle elements. Now, the nerve cells of these spinal roots are very few, when compared with the great number of the ectodermic cells, and yet they are competent to preside over the cells of the ectoderm, although it must be admitted that each nerve fibre is co-related to a group of ectodermic cells.

At the same time, it must not be forgotten that the correlation extends to the spinal cord, where there are cells of coördination, reflexion, and conduction, as well as the cells of mechanical motion and the cells of nutrition. But it is with the cells that affect nutrition that we are at present chiefly concerned. For the existence of such cells we have already brought forward some general reasons that appear to have considerable weight. But nowadays the reasons of experiments go far in the direction of convincing men who will not listen to any other reasons. Have we any experiments in regard to the existence of nerve cells that are co related and correlated with the nutritive work of any cells of the body? I believe we have some experiments in the form of accidents that have happened to the human body. In other words, certain accidents may take the place of experiments.

The third fatal case of gunshot wound of the

spine reported on page 431 of the *Surgical History of the War of the Rebellion*, reads as follows:—Lieutenant George C—, 24 years of age, was wounded, July 9th, 1864, by a conoidal ball, which entered the anterior part of the neck, immediately to the left of the thyroid cartilage, passed through between the roots of the seventh and eighth cervical nerves, and emerged between the spinous processes of the seventh cervical and the first dorsal vertebræ, a little to the left of the neck. Simple dressings were applied. By August 4th the wounds of entrance and exit had entirely healed. *Large bed-sores had formed on the back, arms, and legs.* There was entire paralysis, with involuntary discharges of urine and fæces, and a profuse diarrhœa. The patient died from exhaustion, on August 12th, 1864, thirty-six days after the injury. The autopsy revealed a slight effusion of blood between the membranes and the cord, on the right side and external to the membranes, on the anterior part of the spinal cord. *There was no direct injury to the cord.*

I may draw attention to some significant points in regard to the case whose history I have just transcribed and paraphrased:—

(1) The most significant point is a fact that the reporter has accidentally omitted: It will be seen from the accurate description, that the ball must have destroyed the lower left sympathetic ganglion, because this ganglion lies in the path the ball followed in its passage through the neck. Of course, the function of this ganglion must have been destroyed also. But it must be kept in mind, that the lower sympathetic ganglion of the neck is organically connected with the cilio-spinal axis, whose function must have been affected by the damage done to the neighboring ganglion. And it may be remarked that this damage probably consisted in the disturbance of the correlation between the cilio-spinal axis and the lower cervical ganglion. So that we may say that the cells of the cilio-spinal axis were in a state of intense irritation.

(2) The vertebræ were not injured by the ball, and so there was no direct injury to the cord; and yet there was entire and notable paralysis, as we understand from the report, of the parts below the seat of the injury. This shows that the cord was seriously damaged, and explains the loss of voluntary motion.

(3) The nutrition was extensively disturbed, since there were bed-sores on the back, arms, and legs. Now what was the cause of this disturbance? Did it reside in the sympathetic ganglion, which was the chief structure injured? Did it reside in the cilio-spinal axis, which was indirectly injured on account of the injury to consociated nerve cells? Or, did it reside in the co-ordinated functions of both sets of nerve cells—the cells of the cilio-spinal axis and the cells of the lower cervical sympathetic ganglion? Without formulating an opinion on this important subject just now, let me call attention to the significant facts that voluntary motor impulses are intimately connected with the cells of the cilio-spinal axis, and that *in*voluntary motor impulses are intimately connected with the cells of the sympathetic ganglion. Let me go a step further, and point out the remarkable fact, that voluntary motion and involuntary motion are practically combined in the procuring and digesting of food. Hence, the spinal and sympathetic nerve cells are consociated in the antecedent steps of nutrition. May they not be consociated in the subsequent steps of nutrition? In the metabolism of the protoplasm?

(*To be Continued.*)

Hospital Reports.

HOSPITAL OF ORAL SURGERY.

CLINIC OF PROF. GARRETSON.

Neuralgia.

Gentlemen:—To treat neuralgia scientifically, is to recognize that the meaning of it is pain arising out of a cause; is to make discovery of the cause and to remove it.

Case 1.—Mr. E, aged 60. The case before the class is one of peculiar interest. Six months back I diagnosed a lesion existing in the nerve canal of the lower jaw. The canal was opened and a spicula of bone discovered growing directly across it; the nerve was found jagged, tumid, and broken down in places. The general health of the patient was miserable, as the result of the pain suffered and the opiates taken to relieve the pain. The diseased nerve was thoroughly removed.

The pain is back. The patient insists that he feels it at the original seat. You think it cannot be so situated; that the perception is akin with that which feels pain in a toe that weeks before was buried with an amputated leg. Of this last I am not at all sure. I am in doubt as to whether there are not cases in which the mylo-hyoid nerve perforates the bone.

In the case of the patient before us, one thing is incontrovertible; there is pain; pain so severe that it is not to be endured. There is another fact; the lesion is associated strictly with the third division of the trifacial nerve. Considering the exhausted state of the patient, I shall this morning perform a radical operation. I propose to make a section of the nerve where it appears at the oval foramen. I shall also exsect the jaw. I combine these performances after full consideration. If, in what to-day is done for the case,

relief does not follow, it will never be brought about. I have studied the case pathologically and psychologically; I commit myself to the prognosis given.

Operation.—The operation done combined excision, both of jaw and nerve, and was performed as follows: The patient being etherized, an incision divided the lower lip in its exact median line. Ligatures were placed about the two coronary arteries. Next, a second incision, beginning with the termination of the first, was carried along the shade line of the under surface of the jaw, extending backward and upward, until the zygoma was reached; the facial artery was here tied. A succeeding step dissected the soft parts from the face of the bone, the masseter muscle being lifted from the ramus. Free exposure thus secured, the operator proceeded to remove the bone, after a manner devised by him, of having a rim of continuity and preserving the inner layer of periosteal structure, the latter to be used in covering the seat of section.

In the bone operation the surgical engine is used, the cutting instrument being a circular saw revolved at the rate of at least ten thousand revolutions to the minute. First, an anterior cut was made, commencing from the socket of an extracted lateral incisor tooth, and extending inward to the periosteum, and downward until but a quarter of an inch remained undivided. Second a similar cut was made across the lower face of the ramus. Third, the widely separated cuts were united by means of another carried from behind forward along the base of the bone. Fourth, the section was thrown inward, and the periosteum worked off by means of a chisel shaped knife. This completed the jaw section.

Commencing the second operation by grasping the exposed inferior maxillary nerve with the teeth of a bulldog forceps, the saw of the engine was replaced by an oblong burr, three-quarters of an inch in length by half an inch in diameter. With this burr in rapid rotation, the bed of the nerve was quickly scooped out until the exit from the posterior dental foramen was exposed. Pursuing his new method, Prof. Garretson enlarged the foramen until freely exposing the pterygoid muscle. The nerve, put on the stretch, was lifted from its bed and protected from all its immediate relations in the zygomatic fossa. The conclusion of this part of the operation consisted in passing through the enlarged foramen the blades of a pair of delicate scissors, and in nipping the nerve off just below the oval foramen.

The wound being permitted to remain exposed until a reasonable glaze was secured, the closing commenced by stitching the periosteum over the face of the cut jaw, and next, in accurately adjusting the separated lip and cheek.

So rapid was the process of cure, that the patient left Philadelphia for his home in a distant city, in just thirteen days.

No neuralgia has since troubled him.

Fistula Beneath the Chin, of Four Years' Standing.

Case 2.—The lady before you has, you see, a little sore beneath the chin, a trifle to the right of the median line; this sore has persisted, in spite of much treatment, for a period of four years.

A sore, to defy direct treatment, must have something as a support back of it. This sore, I am sure, has something back of it. I have met, in my experience, with many looking like it, but never one where a directly immediate medication applied to its face could, by any possibility, amount to anything in the way of cure. A moment and you will understand this.

The sore before us is the outlet of a fistulous track. It is not at all a thing having meaning in itself; it exists in some other thing, for which we at once proceed to make search.

With this silver probe I enter the fistula; it leads, as I presumed we would find, directly to the bone. Here we may pass to the mouth. The patient wears artificial teeth, full sets above and below. Removing the lower set there is nothing of unhealthy character to be seen.

I commit myself, gentlemen, by saying that I have never met with a fistulous sore like the one before us, where a tooth, or the root of a tooth, was not at the bottom of it. If here there is found no dental origin, I have to note my first exception.

Confident in my experience, I make a cut along the gum. I dissect the gum from the bone. Convict me, if you please, for a mistake. I confess I never exposed a healthier looking bone. I dismiss the patient that the wound may heal; you shall see the lady later.

* * * This is the patient who, as you will recognize, seemed to convict us of a mistake a few days back. To-day we are to clear up the matter. Ten years back, as I have learned, an operation was performed on this jaw by an eminent surgeon of a distant city, for cure of the condition as we here find it. The bone was exposed and scraped. The result was nil.

The patient being etherized, I make a cut along the shade-line of the neck, directly to the jaw. Let us dissect away, for a little distance from either side of the fistula, the overlying tissue. * * Here is health again, nothing but health. The facial side of this jaw bone is perfect. I will, with extreme delicacy, expose a little of the neck aspect. Here is a small hole. I stick a steel pin into it to make the location. This hole leads to the meaning of the external sore. What I shall do, is the only thing to be done. I shall follow the lead of the hole and see where it goes. Please note how I shall follow the lead. I pick up the penholder-looking instrument, which you all know as the hand-piece of our surgical engine. My assistant, as you see, has armed it with a burr. Now we will put it in motion. It appears as still as though it were lying untouched upon the table, yet at this moment the burr is making ten thousand revolutions to the minute. It is an instrument of magical delicacy. See what it can do, and how it does what it can do.

Operation.—With a few touches, as one would manage a pen, the opening was enlarged, the bone falling into a mass of carious detritus composed of the cancellated structure of the bone. The inside of the jaw, for quite an inch to either side of the hole, was completely broken down. Among the patches removed by the burr, the apex of a tooth root was found.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF LOUIS A. DUHRING, M.D.,

Professor of Dermatology.

Reported by FREDERICK A. TAYLOR.

Eczema Rubrum.

CASE 1.—This case is that remarkable one of universal eczema rubrum, which has appeared on several occasions in this clinic since last spring, when it first entered the hospital. The boy, you will remember, is about eight years old, and has been afflicted since the first year of his life. The disease, as you see, covers every portion of his body, from the crown of his head to the soles of his feet, and to the ends of his fingers. He appeared before the clinic last week, at which time the treatment which he has been undergoing was somewhat modified. For the month previous he had been taking Fowler's solution of arsenic, beginning with small doses, which were gradually increased, until at one time he was taking four minims. This was finally reduced to two minims, the dose upon which he appeared to do best. At the same time he was receiving a mild external treatment, consisting of an ointment made up of equal parts of zinc oxide ointment and cosmoline.

Under this treatment he improved. Last week the arsenic was discontinued, and he was placed on cod-liver oil in increasing doses, also using the oil externally by inunction. I bring him before you to-day to show you the somewhat disappointing result. The redness, you see, has noticeably increased since last week. On the scalp and elsewhere have appeared numerous small, flat pustules. He says he does not feel so well, nor sleep so well.

This treatment, while it answers in some cases, has failed in this instance. We will return to the ointment we were using, but continue the cod-liver oil internally. We will also supplement the treatment by the use of alkaline baths. The ointment will be applied twice daily, and he will appear before you again, that you may see the result of the treatment.

CASE 2.—The patient, a young man twenty years of age, has been suffering from diffused chronic eczema rubrum for nineteen years. He has been in the hospital and under treatment for six weeks. The treatment now consists of the application of the oil of cade to the more infiltrated parts, followed by an ointment of equal parts of zinc oxide ointment and cosmoline. He is anæmic, and is taking tincture of the chloride of iron and quinia internally. He has appeared in the clinic before, and is steadily improving.

CASE 3.—The next two cases illustrate two varieties of eczema. This man presents a marked case of eczema rubrum occurring around the ankles, accompanied with excessive itching. He has been here before, but it was some time ago; dispensary patients are often exceedingly difficult to treat, on account of the irregularity of their appearance. When we saw him last, we prescribed an ointment consisting of thirty grains of calomel to the ounce of zinc oxide ointment, and the disease has improved. We will continue this treatment a week longer, when he may be able to tolerate the use of tar ointment, which will then be substituted.

Eczema Papulosum.

CASE 4.—This young woman appeared at the dispensary three days ago, with a papular eruption on the back of the neck, from the scalp to the shoulders. The skin, you see, presents a dusky reddish surface, is thickened, and is covered with small, ill-defined papules, showing plain evidence of scratching, a point to be noted in making the diagnosis. She has had the disease five months. It is clearly a case of papular eczema.

She has used a saturated solution of boracic acid for three days, which she says has stopped the itching. She will continue the use of it another week, when we will see her again and probably order an ointment of tar, a drachm to the ounce.

Eczema Squamosum.

CASE 5.—This little girl also appeared before the clinic last week. She presents patches of squamous eczema on the side of her face, and also on other parts of the body. In making the diagnosis of this disease, it is to be differentiated carefully from tinea circinata, for which it might easily be mistaken. Squamous eczema is characterized by variously sized and shaped, dry, reddish patches, which are more or less scaly. In distinguishing this disease from tinea circinata it must be remembered that eczema has no tendency to assume circular patches, while tinea circinata has. The edges of the patches of eczema rarely terminate abruptly, while those of tinea circinata generally do. Moreover, eczema tends to become chronic, while tinea runs a rapid, progressive course. In all cases an appeal to the microscope will always decide the question, by showing the presence or absence of the fungus.

As the child is of delicate constitution, spare and pale, and has been troubled with this disease for several years, a constitutional treatment was indicated, and she has consequently been put upon the syrup of the iodide of iron and cod-liver oil. Locally, a white precipitate ointment, twenty grains to the ounce, is being used.

Eczema Rubrum.

CASES 6 and 7.—Here are two middle aged women with chronic eczema rubrum on the legs and feet. The two cases are very similar in appearance. This variety of eczema is most frequently seen upon the legs, appearing in dark red, thickened patches, showing much inflammation, and accompanied with itching. In one of these women the disease also produces a great deal of pain. As she is habitually excessively constipated, she cannot hope for much improvement while that condition exists. We will give her laxative doses, of equal parts of cream of tartar and sulphur, every morning, for a week. Externally, black wash and oxide of zinc ointment have been used, and with benefit. We will now employ, instead, carbolic acid ointment, fifteen grains to the ounce, to be used thrice daily.

Tinea Versicolor.

CASE 8.—In this man you observe over the upper part of the chest a number of faint, yellowish, macular patches, some of which have run together, their surface showing slight furfuraceous desquamation, which is demonstrated by

my scraping the surface with the finger, by which powdery scales are rubbed off. On the upper part of the back the disease is even more marked. This is a typical case of the vegetable parasitic disease, tinea versicolor. The diagnosis of this disease, though very easy, often wins great credit; as for instance where the patient has been receiving treatment for the macular or pigmentary syphiloderm—a not infrequent occurrence.

For the treatment, any of the vegetable parasiticides may be employed, such as baths of potassium sulphide, about two ounces to the bath; sapo viridis, frequently rubbed into the skin; ointments or lotions containing the hyposulphite of sodium, about one drachm to the ounce of ointment or water; corrosive sublimate in the form of a lotion, containing from two to four grains to the ounce. In this case we shall employ sulphurous acid, to be used freely, as a lotion. Before applying any of these remedies, the surface of the skin should be well cleansed with soft soap and water. A cure may be confidently predicted in from three to six weeks; but as relapses are likely to occur, the treatment should be continued for some time after the disappearance of the symptoms.

Case 9.—Here is a man with a formation on the side of the upper lip, which will be very interesting to study. Its appearance, you see, greatly resembles a tubercular syphiloderm. Without history, its appearance alone would scarcely distinguish it from that disease. It appeared about a week ago, having been preceded by some disease of the face which extended from there over the upper lip. Taking hold of some of the stout hairs projecting from the surface, I find that they are very loose, and may be readily extracted without causing pain. This presents the possible error of regarding the disease as syphilitic. In the syphiloderm the hairs are not loosened, as here.

From its sudden development, the absence of the disease on any other part of the body, its first appearance on the side of the face as tinea circinata, and the loose condition of the hairs, the disease is evidently tinea sycosis, or common "barber's itch." This is a peculiar case, in the fact of its location upon the upper lip. I do not recall another case like it. The usual seat of the disease is the chin and neck.

The treatment of the disease consists in the application of strong parasiticides. The hair should be removed from the diseased surface every day. For this patient we shall use as a lotion sulphurous acid in its full strength, three times a day, after which an ointment of the hyposulphite of sodium, two drachms to the ounce, will be rubbed in thoroughly. Our treatment will require two or three months to effect a cure. In the meantime the patient must be warned in regard to the contagiousness of the disease.

Psoriasis.

Case 10.—In the next case, you notice, as the man exposes his arms, that they are nearly completely covered with bright red, coin-sized, rounded, inflammatory patches, some of them running together, covered with large whitish scales. On his legs, as you observe, the disease is even more severe; but the brownish scales which cover the lesions here are not produced by the disease itself, being doubtless due to some ointment which he has been applying. On the body you see the lesions which have most recently appeared; these, you notice, are small, reddish, scaly spots, the scales being distinctly silvery in appearance. It is a typical case of psoriasis. The disease generally appears symmetrically. Since psoriasis sometimes bears a close resemblance to the papulo-squamous syphiloderm, this symmetrical appearance is an important point in making the differential diagnosis; the lesions of the latter disease seldom showing the same tendency to this arrangement.

The case before us is a very acute one. The patient first noticed the disease last August, since which date it has been rapidly progressing. At the present time new lesions are coming out rapidly and abundantly, from day to day. The process is exceedingly active, and constitutes what is known as acute psoriasis. Ordinarily the disease has a much more sluggish course.

We shall advise the use of alkaline baths, and olive oil by inunction, twice a day. In an acute case, such as this, no tar should be used. He will also be ordered to take ten or fifteen minims of the liquor potassæ, well diluted, three times daily, after meals.

Ulcerating Tubercular Syphiloderm.

Case 11.—On this woman's leg and ankle you notice pigmented spots and scars, the results of former ulcerative lesions. Here and there are a few recent ulcers, the size of small coins. The disease is the ulcerative tubercular syphiloderm. The patient, a married woman, forty years of age, has been under my observation for about two years. Mercury and iodide of potassium have been used in various doses. For some time she has been taking iodide of potassium in ten-grain doses, and the biniodide of mercury in one-sixteenth grain doses. This does not serve completely to control the disease. It is often found that when these drugs have been administered together for some time without success, great benefit may be obtained by the use of the iodide of potassium alone, in full doses, from ten to thirty grains. This plan will now be adopted here. There is an interesting fact in the history of this case, to which I wish to call your attention, namely, that six months ago the patient bore a child, which was perfectly healthy and remains so to this day, having never exhibited any syphilitic indication. The anti-syphilitic treatment to which the woman has been subjected for the past two years has doubtless had an effect on the child *in utero*.

Medical Societies.

RHODE ISLAND STATE MEDICAL SOCIETY.

The Annual Meeting of this Society was held in Providence, in December. Dr. C. V. Chapin read a paper on

Malarial Fever,

its cause, effects, and treatment. Dr. Chapin said that the recent appearance of this form of disease among us has given rise to the inquiry as to whether it has at any previous period of our his-

tory been prevalent in New England. Oliver Wendell Holmes, in 1836, said, in an essay, that intermittent fever existed in this section to a moderate extent until the early part of the present century. It occurred, at the time of the Revolution, in Providence, Cranston, and South Kingstown, while other parts of the State escaped. Dr. Mauran, in his early practice, is said to have met with cases of the fever in the north part of this town, and Dr. Usher Parsons knew of cases near a dam which had been built across the Moshassuck river; but for the last fifty years Rhode Island, together with the most of New England, has had complete immunity. About twenty-five years ago, however, malarial disease began to spread eastward from the Hudson, and crept slowly along the coast of Connecticut. In this way the Connecticut and the Thames valleys, as well as those of smaller streams, have become very malarious. New London was visited by the disease in 1878, and Rhode Island was prophesied as the next to suffer.

In 1880 a case appeared at Nayatt, and many others were soon after reported. A few cases also appeared in Providence, all in the vicinity of Mashapang pond. During the past summer a very large number of cases appeared. Of seventy-four physicians, thirty-one reported having cases under treatment, some having a large number of cases; in all about 300 cases were reported. Of these about 187, or 60 per cent., were within half a mile of Mashapang pond; 26 were near the Orient mill, and 8 near the Red bridge; 79 were scattered all over the city. Not a single death occurred within the city limits. The record is very imperfect, and there were probably many more cases which were not reported. Various theories have been advanced, but now the bacterian germs of our enthusiastic German friends are made to bear the blame. The theory of meteorological influences has been dispelled by actual experience.

The disease is often extremely local, and seems capable of being transmitted to a distance by wind or water, the direction often being varied by natural objects, such as trees and hills. Some attribute its existence to electrical disturbances, and others to an excess of ozone. As before mentioned, the fact that these diseases often are such very local endemics would seem to establish this; and additional facts, that the same seems transportable, that the disease has a period of incubation, and that it yields to a specific remedy, is enough to establish without question that malarial affections are caused by some ponderable specific poison.

The Doctor then gave an extended account of several experiments looking to the artificial transmission of the fever to the lower members of the animal kingdom, by injections of swamp water impregnated with bacteria. Also the conditions of the locality conducive to the generation of malarial influences. He closed with a recommendation that the health authorities of the city effect the drainage of the Mashapang pond district, or so arrange that the low-lying districts be permanently covered with water.

THE DISCUSSION.

Dr. H. G. Miller reported several cases of ulceration of the eye, resulting from malarial poison, all of which, after continued treatment, recovered with but little permanent damage to the organ.

Dr. Remmick, whose practice is in Elmwood chiefly, referred to the number of pronounced cases of chills and fever in that vicinity.

Dr. Wm. Shaw Bowen, of this city, reported a unique case of paralysis of the adductor muscles of the larynx, causing complete loss of the voice, that was undoubtedly the result of malaria. The patient had been suffering from chills for some time previous. The voice was recovered after continued treatment with quinine and salicylic acid.

Dr. Batchelder, of Arlington, described his remarkable experience with the results of malaria in his vicinity. He has treated nearly 200 cases of well-marked chills and fever, nearly all of which were on the low ground at the foot of Arlington heights. He combated the theory of the unhealthiness of Mashapang pond, thinking it a libel on that well known place, but admitted Spectacle pond to be partially surrounded by low, swampy ground, that may produce the disease. Dr. Batchelder's remarks were very interesting, and his experience with the disease has been very great.

Several other papers were read, among them being one by Dr. Geo. A. Brug, reporting a case of unusual tolerance of sulphate of morphine. The patient had used morphine for fourteen years, taking it first for relief from pain. Of late she had taken as high as 80 grains between two and five o'clock, P.M. She is now out of danger.

Progressive Atrophy of the Skin.

The *Progrès Médical* (Oct. 29th, 1881) reports that in a clinical lecture, published in *il Morgagni*, Mr. Cantani called attention to a cutaneous lesion for which he could find no analogy in medical literature, and which he designated under the name of *Progressive Atrophy of the Skin*. The case was that of a youth of 20 years, strong, tall, and of good general health, without any nervous or syphilitic history, and who had never indulged in excess of any kind. His attention was first attracted by an enlargement of the right testicle, which, however, gave him no pain, except when horseback riding. A few months later, he noticed the appearance of streaks (vergetures) on the abdomen and over the right inguinal region. These wrinkles or streaks gradually extended up and down, until, at the end of a year, they appeared over the

whole anterior surface of the abdomen, below the umbilicus, and over all the anterior face of the thighs and knees; they also spread over the popliteal regions, and over the lumbar region, where they formed a broad belt; they also appeared at the angle of the right scapula, and over and around the upper part of the arms. Those streaks greatly resembled those produced by an exaggerated distention of the skin; they were not entirely white, but had a bluish red cast. Over some parts where these streaks did not show themselves the skin had a varicose appearance. Prior to this alteration of the skin, the patient had not lost flesh; but after its appearance, the upper portion of his body, the thorax, neck, and face grew stout, while the lower extremities suffered loss.

He also complained of weakness, and when examined he had not had an erection for over two months. Sensibility in all its forms had remained normal. The scrotum showed peculiar conditions: To the left, a varicocele had developed, and the testicle on that side was atrophied; the right testicle also showed signs of approaching atrophy.

The origin of those streaks cannot be attributed to any great distention of the skin preceding a rapid falling away in flesh, because the patient was never obese, and the emaciation of the lower extremities was not very marked; besides, similar streaks appeared over the upper part of the body, where the skin had undergone quite the opposite process. Mr. Cantani compared these lesions to progressive muscular atrophy, and connected them with an analogous medullary lesion.

Mr. Charcot called attention to the following two cases observed at the Salpêtriére, and which bear some analogy to the preceding case.

Case 1.—X., thirty years old, an engineer by trade, and of very excitable disposition, had always, until lately, enjoyed good health; he was in fair flesh, and had not lost in weight. Within the last two or three months he had difficulty in walking; his legs were weak, and he could hardly bring his thighs together; it seemed as if there existed, on both sides, some contraction of the glutei medius and minimus. The lower limbs showed some emaciation, but electrical examination revealed no signs of muscular atrophy. The tendinous reflex in all the limbs was somewhat exaggerated. There were no troubles of sensibility, nor anything particular about the genitals. While examining him, our attention was attracted by streaks having the appearance of small, elongated scars, from one to two millimetres in width. They were of a whitish hue, and around them the pigmentation of the skin was deeper; they formed a slight ridge, and, owing to this and to their color, they bore some resemblance to the cicatrices from scarified cups. Those streaks were very numerous in the lumbar region; they followed a horizontal or oblique course, forming a sort of belt; others appeared, extending over the buttocks in a longitudinal direction. Some could also be seen about the groins, but here they were more faint and less numerous. The patient had always been in fair flesh, and had not noticed when these streaks first showed themselves.

Case 2.—Miss L. presented herself at the consultation on June 8th, 1881. Her troubles dated some three years back. She first experienced continuous pain on the top of the head, radiating to the right and affecting the right ear. Those pains still continued. About a year later, in 1879, pains supervened in the left instep and knee; there was some swelling, and the attending physician declared there was an effusion in the knee.

Since four or five months she had periodical attacks, which came on twice daily, at noon, and toward five o'clock in the evening. These attacks were in the form of a loud cough, resembling a bark, which repeated itself uninterruptedly during a space of from fifteen to twenty minutes. The attacks were generally preceded by a slight hysteric cough, but at times they suddenly came on with the barking cough. There were no convulsions nor fainting fits. The menses were regular.

On examination, the left ovarian region was found painful, and reduced sensibility existed on that side; there was no achromatopsy; marked hyperæsthesia existed over the nape of the neck and the dorsal region along the median line; also on the left side, around the knee, and the tibio-tarsal articulation; these articulations had, anyhow, remained painful, and the patient could only walk with great effort, and on the tip of the foot, the knee being flexed.

This young girl was in good form, had suffered no emaciation, nor had her growth been over rapid. She was accompanied by her relatives and family physician, and we had satisfactory evidence that no distention of the abdomen had ever taken place. For a year past, she had noticed that on her breasts dark lines appeared, which gradually became paler. Examination revealed the presence of radiated streaks converging toward the nipple, around which they appeared in greatest number. Some seemed of more recent date, and were brownish, or of a bluish red. These were two to three millimeters in width, while others, of a dead white, were narrower. Similar streaks appeared over the lumbar region, and the upper part of the buttocks, but none could be found over the abdomen, in the groins, or along the thighs.

The streaks noticed in both the foregoing cases are not located like those caused by a distention of the parts. As a rule, their position might lead us to suppose they were due to pressure from the clothing, or to corrugations or wrinklings of the skin, consequent on movements of the body; but this traumatic origin can only be accepted, if we admit the existence of a peculiar lack of resistance in the skin of such subjects, since like causes have not a similar effect upon the great majority of persons.

Must we here look for some peculiar trophical trouble resulting from a condition of the nervous system, or due to a coincident congenital lack of resistance on the part of the skin? This is a question which, we believe, cannot be decided by a limited number of examples, especially as the history of streaks (vergetures) in general, and in particular their pathogeny, has been but very little studied, except in cases of rapid distention, or growth.

On the Removal of Foreign Bodies from the Ear.

In a paper on this subject, published in the *Medical Record*, Dec. 10th, 1881, Dr. D. B. St. John Roosa, says:—

If you chance to be in the woods with a friend into whose ear an insect has entered, the simplest method of removing it is to pour in some water, warmed by the hand, until the insect can be dislodged. When flies and maggots gain entrance to suppurating ears, the case is one for simple treatment with the syringe, first using some agent which will kill the fly or maggot, such as carbolic acid, Labarraque's solution, or the like; after this, the stream of warm water may be employed. An attempt to remove them with the forceps only makes them more lively and increases the difficulty of their removal. Fortunately, with the advance in our knowledge as to the methods of examining and treating the ear, these cases of maggots entering a decomposing mass deep in the canal are very rare.

With regard to other foreign bodies, as peas, cherry stones, etc., he says:—

Do not be excited when a patient is brought to you who is said to have a foreign body in the ear. Never believe that there is a foreign body in the auditory canal until you have seen it with your own eyes, if you are the person who is to remove it. Take no man's, take no woman's, take no nurse's, take no person's word for this. Very bad results have occurred from the neglect of what seems to be a fundamental proposition. Ears have been syringed—much worse, have been treated with instruments; membrana tympani have been broken, ossicles have been dragged out, labyrinths have been invaded, and meningitis and death have been caused, by neglect of this simple rule. In other words, attempts have been made to remove foreign bodies from the auditory canal when there were none there.

First, then, be sure that there is a foreign body in the ear. Second, remove it by syringing, if possible. Third, wait quietly, if it is so wedged in that it cannot be removed in this manner, until you can procure competent assistance, and then proceed with care and caution, and with such instruments as your ingenuity and the ordinary instrumental collections of aural surgeons will furnish.

Self-Abortion.

The denial, by many authorities, of the possibility of a woman producing self-abortion, has induced Dr. William H. Hardison, of Richland, Ark., to give, in the Louisville *Medical News*, Dec. 10, 1881, the particulars of a few cases which will illustrate the fact that a woman can, not only produce self-abortion, but can do so scientifically. Says he:—

In the fall of 1877 I saw Effie D., eighteen years of age. Four days before my first visit she miscarried, which was followed by puerperal peritonitis, for which latter trouble I was called to see her. Her elder sister gave me the following account of the case: Out of wedlock she had become pregnant. When three months gone in pregnancy, she sought to produce abortion by the advice of an old woman, who told her to get a round stick, as large as she could introduce well into the vagina, round and smooth at one end, then introduce it, and "job" the mouth of the womb with it as hard as she could "stand" it, and to repeat the procedure three or four times a day, until the desired effect was produced. After the third day's "jobbing" she was taken with labor-pains, and within eight or ten hours abortion was completed.

The following case shows the application of scientific means to create self-abortion:—

In the spring of 1879, I was summoned by a servant girl, in great haste, to see Mrs. G., the wife of a railroad man, who she said was in a dying condition. I found the patient unconscious, and while examining for a cause of her condition, I noticed that she was having something very much like labor pains. I inquired of the servant if the patient was in the "family way," but she said she didn't know, and all I could learn from the girl was, that while in an adjoining room she heard the patient scream, and when she got to her she was in the unconscious state in which I found her. I was soon convinced, however, that my patient was having labor pains, and at once made a digital examination; and you may judge of my surprise when I found what subsequently proved to be a small, rounded piece of whalebone, ten or twelve inches in length, protruding from the vagina. Further examination revealed the smaller end lying loosely in the mouth of the womb, which was considerably dilated. I removed the whalebone, and in ten or fifteen minutes the womb expelled a fœtus of perhaps three and a half or four months. My patient soon rallied, and became very talkative and free to *explain*, after the servant girl, who was the only other person in the house, left the room. She explained as follows: Three years previously, while residing in Chicago, she went to full term in her *first* pregnancy, and the child had to be taken from her in pieces. In a year she again became pregnant, when, upon consulting her physician, the same who attended her before, he advised the propriety of an early abortion, to which she and her husband readily agreed. She was then about three months advanced, and the operation was performed by the physician introducing a long, flexible instrument (perhaps a gum-elastic bougie) into the womb and leaving it there; she lying in bed from the time of its introduction until she aborted. Again becoming pregnant, having left Chicago, being about three months advanced, and fully determined on abortion, she decided to undertake the operation herself. I will say just here, that she was a woman of unusual intelligence, and knew more about herself than most women do about themselves. So she procured the piece of whalebone and prepared it very nicely; she then went to bed, and with the forefinger of the left hand found the mouth of the womb, and with her right hand succeeded, after a while, in introducing her improvised probe. In about three hours she began to feel some pain, which gradually grew worse, and the last she remembered until "all was over," was a very severe pain which seemed to extend from her womb to her head.

A very common practice among the negro

wenches of the South inducing self-abortion, is by jumping from high places, such as a fence or gatepost, to the hard ground. I believe that a very large majority of self-abortions, as well as all other superinduced abortions, are produced by the use of oxytocics, principally cotton-root and ergot. I think I am warranted in estimating the proportion of self abortions as at least one-third of all that are superinduced.

Rötheln or German Measles.

Dr. J. W. Byers says, in the *Brit. Med. Jour.*: "There is scarcely another disease upon which the views of authors differ so vastly, as upon rubeola" (rötheln). So wrote Vogel; and although, since the time these words were penned, very great advances have been made in our knowledge of the disease, its exact nature and position among the exanthemata do not seem to be absolutely determined, as is evidenced by the fact that, in the section devoted to diseases of children, at the forthcoming International Medical Congress, one of the subjects that the committee have selected for discussion is the real position of rötheln, and its relation to scarlatina and measles.

Nothing has caused more confusion than the number of names under which the disease has been described. Thus it has been called rubeola, German measles, scarlatina morbillosa, hybrid measles, epidemic roseola. rose-rash, rötheln, etc.

Is rötheln merely a mild form of measles, or of scarlatina, or a combination of both (a sort of hybrid)? or is it a disease *sui generis?* In the *Dictionnaire Encyclopédique des Sciences Médicales*, it is described under the head *Roséole;* and the writers of the article think that those cases which have been published as cases of rötheln, are to be regarded either as measles or abnormal forms of scarlatina, or as combinations which they term rubeolo-scarlatinas (*rubéolo-scarlatines*). These writers state that cases of rötheln are exceptional in private practice, and occur only in the course of certain epidemics; and that they are but little observed except in children's hospitals, where, from the crowding together of patients suffering from the different exanthemata in different stages of their development, hybrid products arise, which are deviations from the normal type of the fevers—in fact, pathological monstrosities (*monstrosités pathologiques*).

I think there can be no doubt that many cases of rötheln are diagnosed as mild or abnormal varieties of measles or scarlatina, especially when epidemics of these fevers are prevailing. Many so-called second attacks of these diseases are probably also cases of rötheln. That, however, rötheln is a specific disease, quite distinct from either measles or scarlatina, and having definite features of its own, has long been held in Germany; and this view has been steadily gaining ground in England, where it has been supported, among others, by Aitken, Murchison, Bristowe, Liveing, Duckworth, etc. That it is quite distinct from measles and scarlatina, seems to be established, apart altogether from its own peculiarities, by the fact that a previous attack of measles or scarlatina, does not give immunity from rötheln (and this was exemplified in my case), and that having had rötheln, does not prevent one from taking measles or scarlatina.

It is only by the careful observation and reporting of cases that our knowledge of rötheln can be rendered complete; and when this is done, it is probable that rötheln will occupy a position as distinct as measles or scarlatina. These were for many years regarded merely as varieties of one and the same disease, and were only finally separated about the middle of the eighteenth century.

Examples of Chorea from Emotional Excitement.

Some interesting illustrations of chorea from this cause are given by Dr. James Russell, in the London *Medical Times and Gazette*, July 23d, 1881:—

Case 1.—A fine developed, high-spirited and passionate, but healthy girl, aged sixteen, was much frightened by a slight cut on her finger, from which much blood flowed; at the time, too, she was in a violent passion with her mother. On the same evening choreic movements came on "in the arm on the same side." In a week the leg became involved, and in a day or two the face and tongue. In the course of fourteen days the choreic movements became greatly exaggerated, and continued to augment in violence, causing general excoriation from constant friction, but without emotional development, for nine days, when she died. Her heart was found healthy, as were all the other organs.

Case 2.—This case related to a girl aged sixteen, in good health, and living under favorable conditions, passionate, but not hysterical, nor in any way nervous; the sounds of her heart pure. She was very much frightened by a fall on her left side, doubling her wrist under her. She soon recovered from the fright, and thought no more about it. Choreic movements commenced on the following day, and became very severe in four days. The disease presented its most violent form for three days, and then gradually subsided.

Case 3.—A chlorotic looking girl, an orphan, aged nineteen, overworked and underfed, not rheumatic, was preparing to emigrate to America, her passage having been paid, when she "spent silly" some money sent over to her to defray her expenses. She was much troubled thereby, and the present illness began, and put an end to her intention of leaving the country. The movement came on gradually, increasing in severity, and at the end of a fortnight or three weeks attained great violence, which for ten days seriously threatened the patient's life, and only subsided tardily.

I may adduce in this connection two other illustrations of a large amount of energy having been released through the application of a comparatively low degree of force, when, as in chorea, the explosive material lies ready to hand, and the restraining influence by which it is normally controlled has been lowered. The incidents did not occur as a primary cause of the chorea, but produced severe aggravation of the disease. In one case a girl, aged twenty-one, had been suffering from choreic movements of a mild character for two days, when her attention was directed to her condition; she immediately

burst into tears, and from that time the movement became greatly aggravated, and speedily developed into a severe form of the disease, with much emotional development. The second instance occurred in an emotional girl who entered the hospital with mild chorea of a month's duration. Ten days afterwards she was much excited by hearing a band of music; she jumped out of bed and was worse directly; the movements became so violent that she was placed in a private ward, and it was a month before any permanent amendment was effected.

Aspiration in Hydatids of the Liver.

In a recent monograph* published in London, Dr. Balding records nine cases of hydatid disease of the liver treated by electrolysis or simple acupuncture, and all with good results. It is to be noted, however, that the tumors were all in young persons, and of small size. Also, in several of the cases, fluid evidently escaped into the peritoneum, which, in the case of purulent contents, would in all probability be fatal. He records thirty cases in which, by means of caustics or incisions, a considerable opening was maintained from the first. The results are not favorable, prolonged suppuration having generally followed, with a fatal result in ten cases. He also records a number of cases in which the cyst was punctured with a small trocar. Out of 155 cases, the fluid on the first puncture was clear in 106, thick or purulent in 49. Among the 49 cases we have 26 cures, 20 deaths, and 3 results not stated—the class in which the contents were clear thus showing 81 per cent. of cures, as against 53 per cent. where the contents were purulent. Again, of the 106 cases in which the fluid was clear at the first puncture, in 35 cases the contents subsequently became purulent, while in 71 there was no evidence that suppuration ever took place. Of these 71 cases last mentioned, there were 58 cures, 11 deaths, and 2 results not given.

The conclusions to which Dr. Balding comes, and which are fully justified by the cases, and the statistics he adduces, are as follows: 1. So soon as the tumor is actually felt, establish the diagnosis by the introduction of a fine aspirator needle. 2. Should the fluid be clear, withdraw the greater part or the whole of it, and close the wound. 3. Should the fluid be purulent, introduce a large trocar, leave the cannula *in situ*, and wash out the cavity once or twice daily, maintaining a free opening and keeping the abdomen well bandaged. Several cases recorded by Harley, belonging to this last class, did not do well till a free opening was made.

Case of Imperforate Anus.

Dr. Luther Sexton, of Hazlehurst, Miss., reports the following case in the New Orleans *Medical Journal*, for December, 1881:—

On the 22d of September I was called to see a baby (Lucy Minor), stout and hearty; weighed 8 pounds at birth, but it had not defecated since its birth, Sept. 20th, though it had been given oil and salts on two different occasions. On examination, I found it fretful, a little feverish, with abdomen considerably distended and tympanitic on percussion. The natural inference of Dr. Purnell and myself was, that there was an accumulation of gas and fæces.

Upon examining the rectum we found it impervious and decided to operate at once, and after debating for some time over the different operations, viz: Littres', Callisen, and Amussat, we finally performed the perineal operation, because we thought we could detect fluctuation in that location, and preferred making the opening at the proper place. I will not describe the operation further than to say I made the first incision by transfixion, and then cautiously dissected up the curve of the sacrum, avoiding the iliac vessels, bladder and peritoneum, till the gut was reached, which presented a dark, glistening appearance. On making an incision into this, at least half a pint of a very dark meconium passed from the child, with a large quantity of gas; this was not offensive. I did not bring down the mucous membrane of the gut and stitch it to the skin, as recommended, because I did not think it practicable in this case. The gut was found rather high up and the parts were so tender that I did not think that sutures would hold, and I expect to keep the parts constantly dilated, to prevent contraction, and think this will answer every purpose. I cannot tell yet what control it will have over the sphincter muscle; in fact, I am not certain it has any. I was cautious in not making the opening too large, as I did not want to wound it, if it was there. The baby is doing well; has its actions naturally; is healthy in every way; no other deformity, nor has there ever been any in the family. The mother and father are well grown and perfectly healthy in very way. It is hardly necessary for me to say I used the ordinary carbolized dressing, with every precaution in regard to cleanliness.

A Case of Anuria of Seventeen Days' Standing.

Dr. C. A. Bryce, of Richmond, Va., writes in the *Southern Clinic* for December, 1881:—

About a month ago I was consulted by James Taylor, colored, factory hand, residing at 305 West Broad street, who said that he could not pass his water, and was suffering some pain and uneasiness in the lower part of his abdomen, or "bottom of his belly," as he located the place of uneasiness. He said his pain was not great by any means, and he wished to see about the trouble as much to satisfy his mind as to relieve his pain, as he had passed no water for *seventeen days*, and felt somewhat concerned as to what was the matter.

A number eight catheter was readily passed into the bladder, and about a pint of urine was drawn off, high-colored and somewhat ammoniacal in odor. Upon questioning the man closely in reference to the time he had been without voiding urine, and doubting the accuracy of his statements, he stated that there could be no doubt about the fact of his not having passed any water for the time mentioned, as he was in Manchester

*"Hydatid Disease of the Liver: its Diagnosis and Treatment." By Mortimer Balding, B.A., M.D. Cantab. London: Harrison & Sons.

on Sunday a fortnight back and passed his urine before coming back to Richmond; before going to bed he tried to pass it, but could not, "and not one drop have I passed until to-day, which is Wednesday, making seventeen days." This man said he had no inconvenience during the entire time, no sick stomach, no headache, and not a single symptom of disease; that he had pursued his daily avocation as a lump-maker in the tobacco factory, and had concluded not to consult a doctor until he had some cause to do so. And finally, that having some pain over his bladder, he had consulted me, thinking the time for professional advice had arrived. He has since passed the usual amount of urine daily, and is, to all appearances, in perfect health. I have not the least doubt in my mind that the man's statements were correct in every particular, and give his name and number, so that any of our physicians may see him and question him further upon the subject, should they feel an interest in the matter.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

LITERARY EXCHANGES.

"*The Century Magazine*," or *Scribner's Monthly*, for January, is a splendid number. The frontispiece is a fine portrait of Louis Adolphus Thiers, and Elihu B. Washburne gives a very nteresting reminiscence of the noted Frenchman. Mary Hallock Foote contributes a finely illustrated paper, "A Provincial Capital of Mexico." An interesting article by Catharine Cornaro, on "The Revival of Burano Lace." Mrs. F. Hodgson Burnett's new story, begun in November, "Through One Administration," is continued, also W. D. Howell's new serial, "A Modern Instance." "The Caverns of Luray," Va., by Ernest Ingersoll, illustrated, and a very interesting article illustrated by Lucy M. Mitchell, on Oriental and Early Greek Sculpture. There are numerous other papers of much interest, which, with the always attractive editorial Topics of the Times, make the January number one exceptionally good.

"*Harper's Monthly*," for January, is, as usual, very good. Its contents, "King Coal's Highway," by G. F. Müller, and "With the Vanguard in Mexico," by W. H. Bishop, are attractive and well illustrated. "Ancient and Modern Venetian Glass," by J. J. Jarvis, is very readable. Constance F. Woolson's novel, "Anne," is continued, and Thomas Hardy's "The Laodicean," comes to a felicitous ending. A fourth paper by Mr. Hatton, and George R. Crooks' paper on the Young Men's Christian Association, have some fine portrait illustrations. F. R. Stockton has one of his characteristic stories. Hon. Geo. Edmunds and Robert T. Keep contribute papers of much interest. The poems are short but good, and "Pastor Dankwaldt," illustrated. The "Easy Chair" contributions of the editor have the never-failing freshness and gracefulness so characteristic of *Harper's Monthly*.

"*St. Nicholas*," for December, is a charming Christmas treat, not only for the young people but for the older readers. Some of the illustrations are exquisite, and all attractive. We can name but a few of the charming articles of this number: "Donald and Dorothy;" "An Angel in an Ulster;" "Stories of Art and Artists;" "Little Polly's Voyage;" "The Hoosier School Boy," etc.

"*Littell's Living Age*" comes, with every week's treasures, unequaled in variety and interest. A model magazine.

BOOK NOTICES.

A Manual of Midwifery. By Alfred Meadows, M.D. Lond., F.R.C.P., late Examiner in Midwifery at the Royal College of Physicians, etc., etc., assisted by Albert J. Venn, M.D., M.R.C.P., Obstetric Physician to the Metropolitan Free Hospital, etc., etc. The fourth edition, revised and enlarged, and illustrated with 137 wood engravings: G. P. Putnam's Sons, 27 and 29 West 23d street, New York. 1882. Cloth, small 8vo, pp. 498. Price $2.50.

As a manual for students and young practitioners, we have always regarded Dr. Meadows' as one of the best in the English language. In this new edition several additions have been made, the entire text has been carefully revised, and matter that seemed obsolete has been omitted. The general arrangement of the work, which makes it especially adapted as a book for ready reference, has, however, not been changed. The illustrations are good, and the general appearance of the book very fair.

Walsh's Physician's Handy Ledger, a Companion to Walsh's Physician's Combined Call-Book and Tablet. Published by Ralph Walsh, M.D., 332 C street, Northwest, Washington, D. C. Price: 600 patients $3.50; 1200 patients $6.00.

The Handy Ledger is designed to assist the hurried and busy practitioner in keeping his accounts. The plan of the book is so simple, yet complete, that but a half hour per week is needed to keep a large practice posted up. It is equally well adapted to the wants of city or country practice, and will accommodate six and twelve hundred names. At the end of the year the entire year's work and nature of attendance can be seen at a glance. It is the most simple, yet complete, system of book keeping we have ever seen, and is sure to repay its cost many times. by saving time and labor, and enabling the busy practitioner to keep his accounts straight.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,

115 South Seventh Street,

PHILADELPHIA, PA.

THE HYGIENE OF SCHOOLS.

The subject of school hygiene is receiving close attention in Cleveland, and the method there adopted is worthy of the highest commendation, and of imitation in other cities. It is based in a general way, and with such adaptations as recommend themselves by the difference of surroundings, on the system of medical inspection of schools in the city of Brussels, Belgium, as carried out by the city Health Department.

The authorities of Cleveland have reproduced the forms of blanks used in Brussels, and have published them, with extracts from the reports of Drs. Janssens and Bonmarriage, explaining their application and utility. We believe copies can be obtained by addressing Dr. L. B. Tuckerman, of Cleveland, to whom we are indebted for a specimen.

It is justly said, in these reports, that with regard to non-contagious, chronic, or constitutional diseases, we believe we do not go too far in saying that the school is destined to be the field where preventive medicine will give the most manifest proofs of its power and win its most glorious victories. If we justly consider the school as a moral agency which should help to depopulate the prisons and galleys, we can equally, from our present point of view, regard it as destined to lighten the budget of the hospitals and almshouses. It is certain that at his home, the child of a laborer, if afflicted with a chronic disease that does not confine him to his bed, will but rarely be the object of that hygienic care indispensable to him; while in the class room, under men both competent and devoted, he can be submitted to an incessant watching and an assiduous care, of which his cure will be very often the assured reward. To care for the children in school so that they shall not become good-for-nothings in the social workshop and in the ranks of the defenders of their country; so that they shall not contribute later to burden the budget of the official charity already too heavy; such is the goal assigned to the efforts of the devoted men who are sacrificing their time and more remunerative occupation to secure to the young generation at school new elements of health, that is, of riches and social prosperity. The subject cannot be too forcibly urged on the attention of medical men in all parts of the country.

THE SPREAD OF SMALLPOX.

On previous occasions we have urged the importance of a new study of smallpox, and the means of its prevention. It is only too obvious that there has been, in the last ten years, an increase of the disease, both in Europe and America.

Does this come from the opposition to or the neglect of vaccination? Does it proceed from the use of inert vaccine matter, or erroneous methods of employing that which is active? Is vaccination itself, however well performed, merely a temporary check to the extension of the disease? Should both vaccination and revaccination be made obligatory and performed at government expense, as an indispensable means of public protection?

These are the questions which, in one form or

another, have often been put in these columns, and still remain unanswered. They have been put also by the most eminent sanitary authorities of the world, and rank among those the solution of which most nearly concerns the immediate welfare of the State. So much prejudice for and against the possible answers exist, that it is far from easy to arrive at a correct conclusion, even when ample statistics are furnished. The result is that while the Doctors debate the patients sicken and die.

An item which ran through the newspapers at the close of December, shows how earnest is the need of decision and action. It was to the effect that the Post-office Department had been appealed to by postmasters in some places to adopt some method of protecting them from mail matter infected by smallpox, "even to the extent of stopping the mail altogether if other means fail." The Department was, said the account, considering the matter.

It is officially stated that smallpox exists in thirty-seven places in Illinois, although in about two-thirds of them the disease is believed to be under control. A telegram from Keokuk, Iowa, of the same date, reports that between thirty and forty of the medical students there have contracted smallpox from a body imported from Chicago and used in the dissecting room of the college.

A number of cases of smallpox were reported in Buffalo, and the disease on the increase, while from New York city and smaller towns in many portions of the Union, the same reports were sent.

With such facts staring them in the face, the Legislatures of the different States will soon have to adopt decided measures to stay the pestilence. The inertness and indifference which characterize such bodies must give way to a rational regard for the sanitary condition of the community. The organization of Boards of Health and Local Boards is the first step. Nothing can be done effectually and permanently without this step. And any brief spasmodic endeavor will be of no lasting service.

Notes and Comments.

A New Application of Electricity in Labor.

At an adjourned meeting of the Paris Academy of Medicine, Dr. George Apostoli read a communication on the above subject. He remarked that at present histology and clinical observation agree in attributing almost all cases of metritis or uterine engorgement to interrupted uterine involution. He, therefore, proposes as a prophylactic agent in an affection which so often follows labor, the adoption of the following new therapeutic method. He thus expresses himself: A woman having been delivered, whether at full term or not, I immediately apply to her uterus a faradic or induction current, generated by a coil made from a short, thick wire, and of progressive intensity. In case of normal and full-term labor, I renew this operation eight or ten times within about six days. In cases of difficult or premature labor, I repeat it fifteen or twenty times through a period of from ten to fifteen days. My object is to aid, hasten, and perfect uterine involution, and thus avoid all the complications incident to slow or deferred convalescence.

The following conclusions have been reached by the study of thirty-two cases within the past two years, comprising eleven premature births and twenty-one full-term deliveries, during the course of which I have performed a total of five hundred electrizations of the uterus while in a gravid or puerperal state: 1. Faradization of the uterus is always absolutely harmless. 2. It invariably has a calming and sedative effect. 3. It greatly reduces convalescence by hastening the involution or retraction of the uterus, which, in general, from the sixth to the eighth day, can no longer be felt under the pubis. 4. By faradization the return and regular exercise of all the functions is accelerated. 5. The patient is spared all the uterine complications incident to labor. 6. Faradization is really a preventive treatment against uterine deviations and such consequences of labor as retroflexions or retroversions. 7. Its effects, I believe, are to reduce lochial discharges. 8. In presence of a faradic current of given strength, uterine contractility greatly varies, and is in the inverse ratio of its inertia. 9. Finally, the effects of faradization on the uterus, as compared with those of ergot, are undoubtedly more prompt and energetic.

In conclusion, I propose the introduction in obstetrical therapeutics, of uterine faradization in every case of labor: First, because it is a

wonderful method, of easy application, readily controlled, rapid and energetic in its effects, always harmless, and capable of being applied or discontinued at will. And second, because its immediate effects tend to restore the patient's health, while it ultimately guards against all subsequent uterine complications.

Pencils of Tannin in Chronic Metritis.

℞. Tannin, grs. 30
Pure glycerine, gtt. 3.

Make four pencils, two inches long.—*Bull. Ther.* (*Bouchardat*).

Malaria and Diabetes.

At a recent meeting of the Academie, M. Verneuil called attention to the relations existing between glycosuria and malarial diseases. Both maladies coexisted in six cases observed in his service, where the patients entered for various surgical diseases (epithelioma of the penis gangrenous patch (plaque) on the heel, tumor, etc.)

The principal memoir on the coexistence of these two morbid states is by M. Burdel, of Vierzon, presented to the Acad. des Sciences, in 1859. This observer found sugar in 80 out of 86 cases of true intermittent fever. The conclusions he arrives at are as follows:—

1st. There exists in malarial fever a veritable glycosuria.

2d. This diabetes is ephemeral; it appears with the fever, persists during its continuance and disappears with it.

3d. The glycosuria of intermittent fever reveals the deep and special effect this form of fever has on the equilibrium existing between the cerebro-spinal and the sympathetic nervous systems.

4th. This explanation, given by Cl. Bernard, is in conformity with the clinical facts.

5th. The more violent and intense the access of fever, the greater the quantity of sugar found in the urine.

6th. When, on the contrary, the attacks become more numerous and less intense; when, in a word, the malarial cachexia becomes established, then it will be found that the quantity of sugar is much less considerable.

The cases observed by M. Verneuil have led him to somewhat different conclusions, and none of his patients had had actual attacks of intermittent for some time previous to coming under his observation. These cases and others have led M. Verneuil to arrive at the following conclusions:—

1st. Malaria frequently engenders glycosuria.

2d. Which presents itself in two forms: the one cotemporary with the febrile attack, and like it, short and fugacious; the other supervening at a period, more or less distant, independent of the febrile paroxysm and permanent.

3d. Permanent glycosuria seems to attack, by preference, vigorous subjects, having some leaning to the arthritic diathesis.

4th. Glycosuria, of malarial origin, appears to be one of the benign forms of diabetes.

5th. Intermittent affections supervening in such subjects, may take on certain characters of malaria or glycosuria, or of both diseases at the same time.

Traumatic lesions may awaken or aggravate the two diatheses, particlarly the accidents of malarial origin.

M. Leon Colin considered that a greater number of observations were needed to confirm the conclusions arrived at by M. Verneuil.

Local Temperature in Acute Abscess.

M. Assaky, interne in Prof. Gosselin's service, has made some very interesting researches regarding the local temperature in the centre of an acute phlegmon. The mode of treatment pursued in Prof. Gosselin's service permitted direct mensuration, and M. Assaky was enabled to draw the conclusions at which he arrives from personal examination in 123 cases.

M. Gosselin generally makes a small, narrow incision, allowing the pus collected to escape, and then injects alcohol at 90°, so that the internal temperature of the abscess could be taken at the debut of the phlegmonous inflammation, and at any period during its evolution. To render the experiment more exact, the surface temperature was taken over the abscess, over the corresponding parts on the other side of the body, and in a certain number of cases in the axilla.

From his researches, M. Assaky has arrived at the following conclusions:—

1st. The temperature in the centre of a subcutaneous acute abscess varies from 37.5° C. to 38.5° C. It oscillates between these two figures, no matter in what region the abscess be situated, and whatever the age and constitutional condition of the patient.

2d. The surface temperature over the abscess is always higher than that on the corresponding part of the other side of the body. Sometimes it is from one-half to two degrees and a half

(Centigrade) higher. In about one-half of M. Assaky's cases it was from one degree to one and one-half higher.

3d. This localized elevation of temperature tends to disappear as the abscess approaches complete cure. Nevertheless, the rise and fall of the temperature proper of the abscess is independent of the general temperature of the body.

Thymol in Diphtheria.

The following mixture containing thymol has, we read in *Le Progrès Médicale*, proven very efficacious in Dr. Warren's hands:—

℞.	Thymol,	gr. ivss–viss	
	Potass. chlorat.,	ʒ iiss	
	Quiniæ bisulph.,	ʒ ss–ʒ j	
	Sp. vini gall.,	ʒ viiiss	
	Glycerinæ,	ʒ ij.	M.

For children, from two to five years of age, a dessertspoonful may be given every hour, or every second hour.

The mixture should be given, if possible, undiluted, in order to obtain its excitant, almost irritant action on the buccal parietes.

This mixture may also be employed as a prophylactic agent against diphtheria and malaria. By the addition of a few drops of tincture of iron to each dose it acts as a tonic and may be employed with success in typhoid fever when diarrhœa is present.

Chloral Injections in Incoercible Vomiting.

Dr. Vidal, of the St. Louis Hospital, Paris, has often used the above with success. In cases of vomiting during pregnancy, these injections, composed of half a pint of infusion of orange leaves and one gram = 15 grains of chloral, are given twice daily. Care being taken to administer them an hour before meals.

Dr. Dussaud, in a recent address before the Medical Society of Marseilles, mentioned the case of a woman, 28 years old, pregnant, who, at regular monthly intervals, suffered from incoercible vomiting; this was subdued by chloral injections. (*Paris Médicale*, Nov. 12th, 1881.)

Ixora Danduca in Dysentery.

The Indian *Medical Gazette* recommends as an efficacious remedy for dysentery the tincture of the fresh root of the ixora danduca. The whole root, and not the bark only, must be used to prepare the tincture, and the fresh root is found to be better than the dried.

To make the tincture, bruise the root, macerate for a week, four ounces of it in a pint of rectified alcohol, express and filter.

A compound tincture may be made by adding to the tincture 3 drachms of long pepper, powdered. The dose is from 30 to 60 grains (Troy), three or four times a day. This is an excellent remedy, and possesess an aromatic, agreeable taste.

Special Reports.

NO. I.—THE MANAGEMENT AND DRESSING OF WOUNDS.

(*Concluded from p.* 26.)

MODIFICATION OF LISTER'S DRESSING.

A useful and convenient modification of Lister's dressing is one used by Dr. James L. Little, of New York City (N. Y. *Medical Journal*, Dec. 1881). He has employed it for some years in torn and lacerated wounds, with much success. The description he gives of it is as follows:—

Having put the parts in a condition for dressing, I wash the wound in a solution of carbolic acid, of the strength of one to twenty; I then cover the parts with a thick layer of borated cotton, and then snugly and evenly apply a simple gauze bandage. At first I used bandages made of antiseptic gauze, but for the past three years have used those of plain uncarbolized cheese cloth. These thin bandages distribute the pressure more evenly over the cotton, and are more easily saturated with fluids than those made of unbleached muslin.

The patient is instructed to keep the outside of the dressing wet with a solution of carbolic acid of the strength of one to one hundred. I frequently employ Squibb's solution of impure carbolic acid, which is of the strength of one to fifty, and which, when mixed with an equal bulk of water, gives a solution of the desired strength.

The parts should be kept at rest, and the dressings may be left undisturbed for several days, unless there is pain, rise of temperature, or discharge through the dressings. These conditions are always to be considered indications for redressing.

In many cases where rubber drainage tubes have been used, they may be removed at the second dressing, and if catgut has been used for sutures, this second dressing can be allowed to remain on for an indefinite period. In a number of cases of lacerated wounds, I have allowed the first dressing to remain on until the wound has entirely healed. In these cases the external use of carbolic lotion was discontinued after the fifth or sixth day, and the dressings would become dry and hard, the wound healing, as it were, "under a scab."

The patient should be instructed to loosen the bandage at once, if any pain occurs.

PREPARATION OF PHENILATED TARLATANE FOR ANTISEPTIC DRESSINGS.

Paris Médicale (November 12th, 1881) publishes, from a Vienna medical journal, Professor

Kaposi's method of preparing phenilated tarlatane, as a cheap and convenient substitute for the more complicated, and often not easily procurable, articles used in the Listerian dressings for wounds.

Pieces of unbleached tarlatane, of convenient size, are immersed in a liquid contained in a covered receptacle, and composed as follows:—

℞. Water,	5 litres,	=	Oxi
Alcohol,	500 grams	=	℥ xvij
Glycerine,	500 "	=	℥ xvij
Phenic acid,	300 "	=	℥ ix, ʒ iij.

M.

These pieces of tarlatane are allowed to macerate in the liquid for about eight days, and as they are required for dressings, are daily replaced by fresh pieces, which are placed at the bottom of the receptacle.

In cases of pressing necessity, an immersion of two hours suffices to destroy all germs which may be contained in the tissue.

Dressings thus prepared should first be rinsed in lukewarm water, and then wrung out, so as to free them from any excess of phenic acid. Otherwise, this might have a corrosive effect on the epidermis, and cause slight symptoms of phenic intoxication, manifesting themselves by black urine.

The edges of the tarlatane strips are lined with cotton wool so as to filter the air, and the whole is covered over with some impervious material, and bound with a strip of net tarlatane, still containing its starch sizing. In drying, these strips adhere to the dressings and skin, and are not disturbed by the patient's movements. As regards the impervious material, Mr. Bœckel has used in place of Lister's *mackintosh*, which is rather expensive, sheets of india rubber cloth, or even *vegetable parchment* (ordinary paper dipped in sulphuric acid); oiled or parafined paper, could likewise be used, and if in two or three thicknesses, would be as resistant as india rubber.

Gummed *silk* is useful in bringing together wide sores, and preserving them from the irritating attacks of phenic acid. It should be fenestrated so as to prevent pus from accumulating beneath it.

SPONGE DRESSING.

The value of the sponge dressing, to which we have already alluded, is explained by Mr. S. Gamgee, in the *Lancet*, November 12, to be simply the application of an old principle, and, perhaps, not a very brilliant one. He observes:—

In the hands of a very careful surgeon, sponges may be used with safety; but it is quite conceivable that the difficulty of cleansing them thoroughly may have proved a source of foulness and its attendant evils, and may explain the abandonment of the use of sponges by all, except a few surgeons. I hold that absorbent and elastic wound dressings, so favorable to drainage and compression, should be burnt after use: and I know of no such dressings more cheap, handy, and efficient than the absorbent and antiseptic gauze and cotton pads, prepared on my suggestion, by Messrs. Southall Brothers and Barclay. But whatever the material used, whether oakum or tenax, sawdust or earth, tow or stypium, salicylic silk or cotton, sponge or pads, is only a question of practical detail. The governing principle is the same. Dry and infrequent dressing, immobility, and pressure are the essentials of wound treatment.

ESMARCH'S PERMANENT ASEPTIC DRESSING.

The eminent surgeon, Esmarch, has carried asepticism to its logical conclusion, maintaining that if a wound is once well and completely dressed antiseptically, it should heal without much further attention, and that changing the dressings is merely incurring new dangers needlessly. The method has stood this test wonderfully. In one of his recent addresses, Prof. Lister himself said of Esmarch's plan:—

I cannot forbear making a passing allusion to the extremely remarkable results which have been related by Professor Esmarch, as obtained by his permanent dressing—results so surprising that they would be incredible were it not for the perfect trustworthiness of the authority that vouches for them. And I would ask those who advocate mere cleanliness, as distinguished from antiseptic practice, how they can reconcile their views with facts such as these? What can be more dirty, in the ordinary acceptation of the term, than a wound left covered up with the same dressing for weeks together, the original blood and serum remaining upon it intact under this "Dauer-Verband?" Yet it is surgically clean, because it is aseptic. On the other hand, the æsthetically cleanly water-dressing is surgically dirty, because it contains elements which give rise to septic changes in wounds.

GENERAL ACCEPTANCE OF ANTISEPTIC DRESSINGS.

In spite of criticism and opposition, there is no doubt but that the aseptic plan of dressing wounds has gained a permanent foothold in surgery. In his address at the International, Prof. Volkmann said:—

In speaking of the open treatment of wounds, I have touched on the opposition which the new doctrine at first met with on so many sides. You all know well how violent this was. Even in science great changes cannot be brought about without injury to numerous individual interests; but I insist that nowadays no serious opposition exists; that there is no surgeon who would dare, at the operating table, or in the treatment of the wounded, quite to renounce antiseptic methods; who calmly and with a good conscience would tread the paths which, fifteen years ago, we all followed like sheep. Even the most

obstinate have had to give way to the great principles of the new era, and often in a much higher degree than they acknowledge to themselves or others; the necessity not only of the disinfection of hands, sponges, instruments, and bandages, but also the necessity of a primary disinfection of fresh wounds, is, I believe, universally acknowledged.

Correspondence.

Alcohol in Diphtheria.

Ed. Med. and Surg. Reporter:—

Inasmuch as the time has not come when the remedy for diphtheria has been found which can be depended upon every time, it is the duty of all who are called to treat it to give the results obtained to the profession, so that different results may be compared. This is a subject which has very greatly interested me, and I have sought in every way that I could to become informed upon the treatment of this terrible disease. I have never met with an epidemic of it, and yet I have had some severe and fatal cases. I have met with some success in the treatment of severe cases, and cannot say but they would have been fatal, had not prompt treatment been commenced and persistently carried out.

A few years since, when Dr. Drysdale published his paper, and it was given in the Medical and Surgical Reporter, with the results attending the use of chlorate of potash in his hands, I was greatly interested in it, and read and re read it a number of times. I carried its teachings out in my practice, and felt very much pleased with my success, and have great faith in chlorate of potash now, as being a valuable remedy in the treatment of diphtheria. I think the failures from its use are to be ascribed to its not being given as freely as Dr. Drysdale urges. I met with numerous cases which recovered under its use. An article from the pen of Dr. Jacoby, of New York, in which its poisonous action was described, with some fatal results attending its use in large doses, brought to my mind a case that came under my care, of a clergyman who was taken with this disease, and to whom I was called. I prescribed for him the saturated solution of chlorate of potash, to be taken in tablespoonful doses every two hours. The gentleman was one of those impulsive men, and thought if a little would do good, that double the quantity would do more. At evening the medicine was gone, and had to be renewed. The next day, towards evening, he was taken with vomiting, and I could not tell why, for he had appeared better in the morning. The urine which he voided was as dark as coffee, and caused me some apprehension. The potash was discontinued and the next day he was improving. From Dr. Jacoby's article I learned that my patient had taken too much potash, and there was danger of acute nephritis supervening. Since that time I have been careful to have my directions followed more closely.

I read of Dr. E. N. Chapman's success with alcohol in the treatment of this disease, and resolved to give it a trial when a case should present itself. The first case was myself. During the past winter of 1881 I was taken with a severe chill at night, which lasted part of the night, followed with a high fever. My throat was not much sore, and I did not know what was coming upon me. I inspected my throat and saw several large patches of membrane. covering both tonsils; resorted to the use of whisky, taking every hour two large tablespoonfuls for twenty-fours before I began to feel better; and when I did begin to improve I discontinued its use; the membrane came off my throat, but it was several weeks before I got strong and well.

My second case was a little boy of six or seven years, who had moved from a town where it had prevailed as an epidemic, and several had died. When I first saw him he was feverish, but did not complain of his throat, and I prescribed a fever mixture and thought it a case of malarial affection. The next day he appeared so much better, I was requested not to call. In the evening, his father called to see me and get some more medicine, and I concluded to see him the next morning. On seeing him, he did not appear any worse. He said his throat was sore, and I examined it, and was surprised to see so much deposit in the throat and covering the tonsils, from so little constitutional disturbance. I immediately began the use of whisky every hour, in two teaspoonful doses, and continued it until the system came under its influence, the membrane came off the throat, and he began to improve. A few weeks after, his eyelids were partially paralyzed, and he could hardly hold up his head, from muscular weakness. His head would tip from side to side, and he could hardly speak, and his eyes were squinted. This continued for a few weeks, when he began to recover his strength.

The third case was my son, a lad of nearly twelve years, who came down with the diphtheria after school, and when inspected, his throat, the tonsils and fauces, were covered with a thick membrane. I gave him the same treatment, and did not remit the whisky until his system came under its influence, when the membrane would come off in flakes, leaving a deep ulcer on the tonsil, but the membrane did not form again, and he recovered, but was weak and trembling for some days; he improved under the use of quinine and iron. I used the chlorate as a gargle all the time, and gave some of it internally. I want to impress upon the profession the importance of giving special attention to the throat when first called, and when convinced of the nature of the disease, to begin at once the use of some alcoholic stimulant, and push it until the system is saturated, and not to desist until that point is reached. You will be surprised at the amount that can be taken before the system will feel its stupefying effect. I hope all who have to treat this disease will give this remedy a trial, and see how well you can control this fearful disease. Let me quote a note from Dr. F. C. Roberts, of Fort Madison, Iowa, in *Gaillard's Medical Journal*:—

"While cauterizing a patient's throat, the victim coughed, throwing the diphtheritic membrane all over my face. After a few days I fell

ill with the disease and suffered severely. I used the ordinary routine treatment, but became gradually weaker. The membrane in my throat nearly suffocated me. At last, becoming very weak, I sent for some whisky to use as a stimulant. A drink of it nearly suffocated me, and I strangled badly, and coughing hard, ejected a large quantity of membrane in an almost cooked condition; immediately relief followed, and in a short time I again used the whisky; this time as a gargle, and the sensation of ease and comfort following induced me to use it frequently, and in a few days I was completely cured.

The second case was as follows: I was called in consultation with Dr. Hoffmeister; found the patient, a boy of fourteen years, suffering the same as I had, only much weaker, and nearly black in the face, from suffocation. Remembering my own experience, I advised the use of stimulants internally, and the following gargle:—

℞. Potassa chloratis, ℥ ss
Alcohol,
Aqua rosæ, āā ℥ ij. M.
To be used frequently.

Immediate improvement followed. Since that time I have used the alcohol very freely in diphtheritic cases, and always with the most favorable results." H. N. Burr, M.D.
Walworth, N. Y.

Suggestions in the Treatment of Traumatic Tetanus.

Ed. Med. and Surg. Reporter:—

On Friday, Nov. 18th, 1881, Thomas W. accidentally discharged his gun, carrying away the palmar portion of right hand and wrist. I was at once summoned, and found a fearfully lacerated wound, the flexors of the thumb, the palmar aponeurosis torn in shreds, and the tendons of the flexor muscles of the forearm were more or less involved. Although the destruction was very great, hemorrhage was at the mininum, the larger blood vessels—palmar arch, etc., seemed not to have been injured, therefore I resolved to make an effort to save the hand. I cleansed the wound, carefully adjusted the detached parts, applied bandages, introduced the catheter, and left my patient with instructions to take thirty drops opii. tinc., should he have pain. It was not needed; my patient rested easily. The two following days, a water dressing was used; after this carbolized oil, and I must say, that I never knew a wound to do better; suppuration was established, and when the bandages were removed, the injured part would be found bathed in a healthy, cream-like pus.

I was highly elated, thinking my patient would make a speedy recovery, but I was doomed to disappointment, for on the tenth day he complained of what he termed a cramping pain in the pit of the stomach, and some difficulty in deglutition. I recognized tetanus, and expected to find a change from the former healthy appearance of the injured part, but on removing the bandage, I found all in as good condition as I could wish—the usual quantity of healthy pus, rapid granulation, nothing like undue inflammatory action. Most surgeons tell us that, when tetanus makes its appearance, the wound has been in, or assumes at the time, an unhealthy condition. Dr. Abernethy, I think, relates a case where, after free suppuration, the spasm and rigidity disappeared, implying that it had been suspended during the attack; not so in my case. During the whole period in which there was the most violent tetanus, the wound progressed rapidly toward repair, the suppuration, and healing never for one moment ceased.

On the eleventh day since the injury I found Mr. W. in a very critical condition; tonic rigidity of the muscles of the neck; almost unbearable pain, especially severe inferior to sternum; jaws clenched; inability to swallow; risus sardonicus, and bathed in profuse perspiration. The mind was perfectly clear, and altogether he was a horrible spectacle. I will call attention to a prominent symptom, viz., an uncontrollable desire for water, of which he could not swallow a drop, or at least it would not enter the stomach, stopping, as he said, two-thirds the way down, where it would remain for a moment, and then be expelled with force. In the attempts to swallow, asphyxia would almost take place, and in my efforts to prevent strangulation I discovered something new, or, at least, new to me, and will give it, for the benefit of those who may be called to manage a similar case:—

My patient was choking, from a spoonful of water he had attempted to swallow. I placed my hand on the back of the neck, pushing the *whole body* well forward, hoping to thus empty the pharynx. Understand, I did not flex the neck, I pushed the whole trunk well forward, and, greatly to my surprise, he exclaimed, "It is gone," and sure enough the fluid had passed the cardiac orifice. Acting upon this hint, I immediately gave a dose of potass. bromide, pushed the *body* well forward; it passed into the stomach without producing strangulation, a hitherto impossible operation. By resorting to this manœuvre, food and medicines were administered for three days, or until relaxation took place sufficiently to allow deglutition in the usual manner. Fortunately for the community, and unfortunately for me as an investigator, tetanus is of such rare occurrence in my practice, that it may be years before I can prove or disprove the efficacy of this plan in other cases; but, as the plan is easily tried, I would advise all to give it a trial, and I would be pleased to hear the result.

I will not attempt to advance a theory; yet I have thought that in pushing the body well forward, a position was gained which favored the relaxation of the diaphragm sufficiently to allow the opening of the cardiac orifice, the seeming point of obstruction. The muscular fibres of the œsophagus seemed not to be affected by the spasm, at least not until the water had remained in it sufficiently long to produce it. I am content to let fine-spun theories alone, and rest satisfied with the truth, pure and simple. The administration of medicines and food by any other channel than the mouth is attended with considerable trouble and inconvenience, not saying anything about the shock to the modesty of a delicate female; therefore, if my experience in this case should hold good in others, the physician, as well as the patient, will be saved considerable annoyance. I adopted the following plan

of treatment, viz. :—For the first ten days, gave morph. sulph. per mouth and hypodermically, in sufficiently large quantities to mitigate the pain; on the second and third days, the morning of each, one grain of the drug was given hypodermically, and repeated in one hour; during the balance of the days, one fourth grain was given, on an average of every other hour. My instructions were to allay the pain without regard to the interval, and the nurses religiously followed directions. In addition, twenty grains potass. bromid. was given every third hour; ice to the spine, the application of which seemed very grateful to the patient. This plan was continued until relaxation began to take place, when twenty-grain doses of chloral hydrat. were substituted for the morphia; and I suspect after this substitution the recovery was more rapid. The bowels were occasionally moved with ol. tiglii and calomel. The final result was complete recovery.

Penna.

A New Dissecting Knife.

ED. MED. AND SURG. REPORTER:—

The instrument I bring to the attention of your readers is made from a rod of steel, 19 cm. long and 7 cm. square, tapered down on each side of the middle point, for a distance of 4 cm., to the thickness of a stiff spatula, the central spindle-shaped piece forming the handle. The ends of the rod, 5.5 cm. long, are forged into moderately thin, springy blades, one being sharpened at the point and along the edges for a distance of 3.5 cm., the other being rounded at the point, and not sharpened. All the edges and angles are carefully rounded and polished, the cutting edge, of course, excepted. The knife, as a whole, is bent into a double curve, making a clavicular shaped instrument.

This was devised for use in dissecting, and with it work may be done much more quickly and satisfactorily than with the ordinary scalpel. The knife is held like a penholder, the proximal end of the blade being held between the thumb and index finger, the back resting on the middle finger, the concave side being superior. The knife is very nicely balanced, and, owing to the shape of the handle and curve of the blade, can be firmly held and lightly held in the proper position, so that great precision may be obtained in its use, and a long sweeping cut can be made, using both point and edge; whereas in the scalpel, only the point is available, the strokes being short and the action being one of picking more than cutting. The blade of a scalpel is so set in the handle that it stands nearly vertical when held in the usual manner, and so the motion is limited to the fingers. In this knife the blade is so set in relation to the handle that we get a free action of the fingers and wrist; and as but little effort is required to hold it, the hand does not become cramped and tired.

It is especially useful in dissecting away the fascia, in following the course of nerves, arteries, and veins, and in separating individual muscles, especially the long muscles of the extremities and back.

The unsharpened blade is useful as an exploring probe and as an elevator, and is often more safely used than the sharp blade in dissections of the vessels. In demonstrating, it is useful as a pointer and elevator.

This instrument will be found of use in surgical operations. To make it more applicable to this purpose a small hole was made in the unsharpened blade near the tip, and a groove was made, running lengthwise of the blade, so that the probe could be used as a ligature carrier or director. In exploring sinuses and similar cavities the probe may be used to advantage as a sinus dilator, since there are no sharp edges to sever arteries or veins. For ligating arteries for aneurism, or veins for varices, the knife may be used for making the necessary incisions, and the other blade will serve to carry the ligature under the vessel. It is also useful in operations for lacerated cervix, for those of the mouth and throat, and many minor operations. Being forged from a single piece of steel, there are no crevices in which septic matter can lodge, and it is easily cleaned.

Boston, Mass. CHAS. EVERETT WARREN, M.D.

Investigations with Regard to School Children.

ED. MED. AND SURG. REPORTER:—

Having been for some time interested in the relations which obtain between brain growth and body growth, I undertook, with the sanction of a Committee of our Board of Education, an inquiry to discover, if possible, how prevalent, among the children in our higher public schools, were those symptoms which men like Drs Day and Richardson, of London, and Drs. Thomas, Goodell, Hamilton, Beard, and others in this country, are wont to attribute, in no small degree, to the methods of intellectual training now standard in our schools.

The intention at first was, to secure information with regard to the large number (23 per cent. of the girls and 18 per cent. of the boys), that had withdrawn from one cause or another, from the High school, during the school year.

Later, it was thought best to gather, for purposes of comparison, information with regard to such recent graduates, and pupils still attending school, as lived in the immediate vicinity of those who had withdrawn, and who could thus be conveniently found.

Statements were thus obtained from the parents of two hundred and twenty-six pupils; forty boys who had withdrawn; ninety-six girls who had withdrawn; fifty eight girls still attending, and thirty-two recent graduates.

These statements showed that 37 per cent. of the boys and 75 per cent. of the girls had withdrawn, either wholly or in part, by reason of impaired health. Moreover, it appeared from these statements that, *while attending* school, many

pupils suffered from abnormal symptoms from which they were free, or nearly so, during vacation. The percentage is shown in the following table:—

While at School.	*Boys who left.*	*Girls who Left.*	*Girls still Attending.*	*Graduates.*
Health not so good	50	80	64	84
Lost appetite	23	46	38	38
Lost sleep	10	27	26	22
Had headache	45	72	55	69
Eyes weak	23	36	31	38
Eyes failed since entering	8	12	17	16
Had back or sideache	..	52	31	25
Had nervous troubles	..	44	36	66
Had hysteria	..	11	5	16
Complained of stair climbing	..	52	41	6
Menstrual symptoms known	..	42	30	13
Menses deranged while at school	..	62	57	46
Menses frequent or profuse	..	31	27	..
Menses scanty, irregular, painful	..	48	44	46

Cases where menses were both profuse and painful, were counted simultaneously in each class. As nervous troubles were classed hysteria, tremor, chorea, unnatural irritability, melancholy, etc., inquiry was made with regard to the amount of time pupils were in the habit of spending in study, outside of school hours. Also, with regard to the girls, what were their habits as to social recreation, etc. Collating the cases, as to hours of home study showed that for some reason, the girls habitually spent longer at their lessons than the boys. The ratio being as follows:—

Hours of home study	2	2–4	4–6	6
Boys, per cent.	25	65	5	3
Girls, " "	8	47	38	6

And that the percentage of abnormal symptoms increased among the 186 girls, as a rule, side by side with the increase of home study, thus:—

Hours of home study	2	2–4	4–6	6
Health power, while at school, per cent.	29	70	93	100
Lost appetite "	7	44	47	64
Lost sleep "	7	18	34	64
Had headache "	22	62	81	100
Had back or sideache "	14	34	54	45
Had nervous troubles "	7	33	61	91
Had hysteria "	—	5	19	18
Had eyes weak "	29	39	36	45
Failed since ent'g high school, "	14	13	18	17
Menstrual symptoms known, No	5	40	31	9
Menses deranged at school, per cent	20	50	31	33
Menses frequent or profuse, per cent	20	28	26	11
Menses scanty, irregular, painful, per ct.	—	35	71	33

Showing that so far as these 186 were concerned, the home study was an active factor in producing these symptoms. The better average health of those who indulged more freely in social recreation was almost equally marked.

Of course, so few cases cannot be cited as proving general laws, but they indicate a fruitful field for statistical inquiry, and it is to be hoped that the Board of Education here will conclude to continue the investigation, as has been proposed, till information shall have been obtained with regard to all who are at present attending our High Schools.

The remedy for these evils in our schools, evils which all acknowledge who have given the subject thought, lies in sytematic sanitary supervision of our schools by competent medical men. There must be some means provided, by which the physical effects of various systems of mental training can be thoroughly studied and regularly recorded.

The system which has been working so successfully in Brussels, Belgium, for the last seven years, should receive the careful consideration of students of sanitary science. By systematic medical inspection of the schools, they have been able to stamp out epidemics of the zymotic diseases among children.* And by special attention to those who, though able to attend school, are yet feeble, by reason of inherited dyscrasiæ; by regulating their brain work, and adapting their exercise to the needs of their physical condition, and by administering to such of them as are indigent, *cod-liver oil*, in the schools, they obtained, in two years, the following results†:—

Disease.	*Cured.*	*Better.*	*No. Treated.*
Scrofulous disease	72	156	286
Lymphatic "	34	263	366
Rachitic "	9	57	84
Anæmia	77	251	406
Chronic Bronchitis	6	4	21
Total	198	731	1163

Though their system, in all its details, would no doubt be unadapted to our American people, their results should prompt us to earnest effort to provide some efficient means to a like end.

L. B. Tuckerman, M.D.

East Cleveland, Ohio.

Opium Habit.

Ed. Med. and Surg. Reporter:—

Gradually reduce the amount of opium taken and increase the amount of nutritious food and tonics. The indications of treatment are: 1st. Gradually reduce the dose. 2d. Relieve the great nervousness, insomnia, prostration and suffering. Bromide of potassium will not do this, because in these cases there is anæmia of the brain, and it is contraindicated in anæmia of the brain. It may cause a little sleep in very large doses, but these irritate the stomach, they also increase prostration and suffering. The same remarks apply to chloral. They should never be depended on alone. Probably, in extreme insomnia, rightly combined with other nervines, they may do; but alone, I have seen them cause delirium, and I think are sometimes dangerous in these cases, by increasing the anæmia. Veratrum viride will not answer the second indication, nor will coca, nor oxide zinc. Nit. amyl is reported to do well and cause sleep; curara might be tried. If some medicine were discovered that had the same stimulant, excitant, exhilarating and sedative effects as morphia, and being a tonic without having any deleterious effects like morphia, nor checking the secretions and nutrition, it

* Congrès International d'Ensignement Rapport. de M. Le Dr. Janssens, Bruxelles, 1880

† Congrès International d'Ensignement. Rapport de M. Le Dr. Bonmariage: Bruxelles, 1880.

would answer admirably as a morphia antidote. The following combination comes as near it, and meets the second indication better than anything I have seen:—

℞. Con. tinct. cannabis indica, gtt. 10
Narcotic.
Con. tinct. cypripedium, gtt. 15
Anti-spasmodic, nervine, tonic, narcotic, diaphoretic.
Sulphate hyoscyamia, gr. $\frac{1}{48}$
Soporific, sedative, narcotic diuretic, and laxative.
Con. tinct. humulus lupulin, gtt. 15
Nervine, hypnotic, febrifuge, diuretic and tonic.
Con. tinct. lycopus, gtt. 20
Astringent, styptic, sedative, and tonic.
Con. tinct. pulsatilla, gtt. 5
Nervine.
Con. tinct. hamamelis, gtt. 15
Astringent, tonic, sedative.

Mix above thoroughly, and as Shakspeare says, all the sedative herbs of the world will "Medicine him to sleep." I have tried above, and know it will do. It will entirely substitute the morphia. They are B. Keith's concentrated tinctures. Dose of above, gtt. 10 to 1 to 2 ʒ s.

To meet the third indication, to build up patient's strength and fatten him, give tonics of iron, phos., strychnia, etc., and give him hydroleine. Adopt Dr. Weir Mitchell's system of excessive feeding, and fatten him. Give as much good food (and often) as the stomach will bear.

John M. White, m.d.

Picrotoxine in Night Sweating.

Ed. Med. and Surg. Reporter:—

During my last two terms of service at the Episcopal Hospital, I have exclusively employed the active principle of cocculus indicus, picrotoxine, in the treatment of night sweating in phthisis and other diseases. My success with this substance has been so decided, so far superior to that previously obtained by the mineral acids, belladonna and ergot, singly and combined, that I can no longer postpone the public expression of my opinion concerning it.

My attention was first called to this use of the drug by a quotation from an article in the *Practitioner*, by Dr. William Murrell, who, after extended trial, found it the best substance he had ever employed for night sweating. The dose used by Murrell was from gr. $\frac{1}{180}$ to gr. $\frac{1}{60}$; the latter amount, four times a day, being the largest dose administered by him. My custom has been to give a pill containing gr. $\frac{1}{80}$ at bedtime, which dose may be repeated once or twice during the day in obstinate cases, and, at my suggestion, the firm of McKesson and Robbins, of New York, have added such a pill to their list.

As above intimated, I have not employed this drug solely in the night sweats of phthisis. I recall a case of chronic pleurisy in which, the effusion having been absorbed, convalescence was unaccountably retarded and prostration was so extreme that a latent, incipient phthisis was suspected. The skin was bathed in perspiration during the greater portion of the twenty-four hours, and this being the only discoverable morbid condition, I resolved to treat it with picrotoxine. It was promptly checked and convalescence set in immediately.

I have employed the drug in nearly one hundred cases.

Philadelphia. Frederick P. Henry, m.d.

Ophthalmia.

Ed. Med. and Surg. Reporter:—

I desire to communicate to the profession, through the medium of your most worthy periodical, a simple, but effective mode of treating scrofulous conjunctivitis. The patient, a lady, Mrs. C., age 23, the mother of one child, of scrofulous diathesis and nervo-sanguine temperament. She had been subjected to repeated attacks of violent sore eyes; in fact, her eyes have not been perfectly well in ten years until quite recently, though her general health has been excellent. The present attack began about the first of April, 1881, and continued almost to complete blindness, until November 25th, 1881, when I began treatment by directing strict dietetic and hygienic regime. They had essayed every available remedy without benefit, and had concluded that she was doomed to eternal darkness. I administered the following simple receipt, per orem:—

℞. Pot. iodidi, ʒ ss
Syr. sarsar. co., ℥ viij
Tinct. cincho. co., ʒ ij
Aqua pluvialis, q.s. ad Oj. M.
Cap. coch. mag. ter. die.

I ordered the following collyrium to be applied to the eyelids, twice daily:—

℞. Zinci. sulph., gr. v
Aqua pura., ʒ j.
Ft. sol.
Use as directed.

The above was the entire therapeutics of the case, which improved rapidly, ab initio, and she is now, December 25th, 1881, perfectly well, and can see as well as she could before the first attack.

Although an isolated case does not constitute a substantial criterion, I am confident that the above was not a mere recovery, but an absolute cure. A. M. Hathcock, m.d.

Hickory Valley, Ark.

Multiple Births.

Ed. Med. and Surg. Reporter:—

The papers seem to be somewhat excited over the fact that a Mrs. Casey, of New York, has given birth to three boys. Well, this is all well enough, for such cases are not common, and boys are rather scarce; but this is not by any means the first case of the kind. I know of a case that I have often thought ought to be reported, but so far as I can learn, it has never yet been reported.

A Mrs. Howitt. of Drumore Township, Lancaster Co., Penna., gave birth to three healthy boys—the three weighing, according to my recollection, twenty one pounds—in May or June of the year 1856. When I visited that neighborhood in 1876, I made inquiry concerning the boys, and I was informed that they were all living and doing well. Triplets usually do not live many months, but these boys were twenty years old in 1876, and I have not heard of the death of any of them since. George T. Dare, M.D., was the accoucheur on that occasion. Dr. Dare resides in Oxford, Chester Co., Penna.

Some twelve or fourteen years since, a lady in Fayette, Howard Co., Mo., gave birth to four children, two boys, I believe, and two girls. Two of them died in two or three weeks, and so far as I have learned, the other two are living now.

Maryville Mo. JOSEPH B. MORRISON, M.D.

The Vaccination Question.

ED. MED. AND SURG. REPORTER:—

In the discussion on vaccination, in your journal, E. M. S., says: "I know that some persons are *temporarily insusceptible* to the effects of vaccine virus. As a proof of this, I wish to make the following statement: In the spring of 1881 I vaccinated a lady and myself, both from the same "ivory point;" (both of us had been vaccinated in childhood). She *did not* take; mine *did*, beautifully.

In December, 1881, there being a case of smallpox in the town, I concluded to vaccinate again. The lady was anxious to try the experiment, and I vaccinated, as on the former occasion, both from the same "point;" the result was, mine *did not* take, hers *did*. This shows conclusively that some change had taken place in the lady's system, after the operation of the spring of 1881, or the result in the autumn or winter of the same year would undoubtedly have been similar.

I have in my mind the case of a lady upon whom vaccination would never take, the operation having been performed many times. On one occasion the skin was opened and the virus inserted, without any effect whatever. This lady's brother has two children that I have vaccinated five times, each, without any good resulting. I would ask, can the insusceptibility be transmitted? THEO. A. WORRALL, M.D.

NEWS AND MISCELLANY.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, October 1st, 1881, to December 31st, 1881.

Hebersmith, Ernest, Surgeon. Relieved from duty at San Francisco, Cal., and placed on waiting orders, Nov. 7th, 1881. Relieved from waiting orders, Nov. 26th, 1881.

Vansant, John, Surgeon. Granted fourteen days' leave of absence, Oct. 18th, 1881. To proceed to San Francisco, Cal., and assume charge of the Service at that port, Nov. 8th, 1881.

Miller, T. W., Surgeon. Granted leave of absence for seven days, Oct. 6th, 1881.

Purviance, George, Surgeon. To proceed to Boston, Mass., and assume charge of the Service at that port, Nov. 8th, 1881.

Austin, H. W., Surgeon. To proceed to Galveston, Indianola, Corpus Christi, and Brownsville, Texas, as inspector, Oct. 17th, 1881.

Fisher, J. C., Passed Assistant Surgeon. To proceed to Yorktown, Va., as inspector, Oct. 14th, 1881. Detailed as member of Board for the Examination of Keepers and Crews of the Life Saving Service, Third District, Nov. 18th, 1881.

Goldsborough, C. B., Passed Assistant Surgeon. Detailed as member of Board for the Examination of Keepers and Crews of the Life Saving Service, Fifth and Sixth Districts, Nov. 2d, 1881.

O'Connor, F. J., Assistant Surgeon. Granted leave of absence for fifteen days, on account of sickness, Dec. 23d, 1881.

Guitéras, John, Assistant Surgeon. Granted leave of absence for ten days, Dec. 5th, 1881.

Benson, J. A., Assistant Surgeon. Granted leave of absence for twenty-one days, Dec. 7th, and 21st, 1881.

Banks, C. E., Assistant Surgeon. To assume temporary charge of the Service at San Francisco, Cal., until the arrival of Surgeon Vansant, Nov. 7th, 1881.

Carmichael, D. A., Assistant Surgeon. To proceed to Baltimore, Md., for temporary duty, Nov. 2d, 1881. To rejoin his station (New York), and thence proceed to Pittsburgh, Pa., and assume charge of the Service at that port, Nov. 18th, 1881.

Bennett, P. H., Assistant Surgeon. To proceed to Boston, Mass., for temporary duty, Oct. 21st, 1881.

Peckham, C. T., Assistant Surgeon. To report for temporary duty to Surgeon-in charge, Boston, Mass., Oct. 21st, 1881. To proceed to Vineyard Haven, Mass., for temporary duty, Nov. 4th, 1881. To rejoin his station (Boston), and thence proceed to New York, reporting for duty to Surgeon-in-charge, Nov. 9th, 1881.

Ames, R. P. M., Assistant Surgeon. To proceed to St. Louis, Mo., for temporary duty, Oct. 21st, 1881. To proceed to Evansville, Ind., for temporary duty, Dec. 24th, 1881.

Devan, S. C., Assistant Surgeon. To proceed to San Francisco, Cal., for temporary duty, Oct. 21st, 1881.

Urquhart, F. M., Assistant Surgeon. To report for temporary duty to Surgeon-in-charge, New York, N. Y., Oct. 21st, 1881.

APPOINTMENTS.

The following candidates, having passed the examination required by the Regulations, were appointed Assistant Surgeons by the Secretary of the Treasury, Oct. 20th, 1881:—

Philo H. Bennett, M.D., of New York.
Cyrus T. Peckham, M.D., of Massachusetts.
Robert P. M. Ames, M.D., of Pennsylvania.
Spencer C. Devan, M.D., of Missouri.
Francis M. Urquhart, M.D., of New York.

Philadelphia Centenarians.

The *Public Ledger* of this city keeps a record of persons of unusually advanced age who pass from among us. The following are its comments:—

The deaths of 13 centenarians were recorded in the *Ledger* during the year (4 more than in 1880); of these there were 10 women and 3 men, Annie Granleas, Kate Kelly, and Rachel Mahorn, aged 100; Mary Winn, 101; John Monaghan, Hugh Lynch, Mary Miller, and Sarah McKay, 102; Elizabeth Quin, 104; Daniel Webster, 105; Hester Reckless, 105; Margaret Gasaway, 106; Daffy Burton, 115. Six of these died during the first half of the year, and have heretofore been noticed. The others are Annie Granleas, widow of the late Thomas Granleas, who died suddenly, September 12, aged 100 years; she was buried from the residence of her grandson, William Rahlfing, on September 16; Mary Miller, who died November 14, at the residence of her son, John N. Miller, No. 1231 South Thirty-first street, aged 102 years. She is said to have boasted that she once cooked a breakfast for General Washington, but that is hardly likely, unless she learned cooking very young. Catharine Kelly died November 26, aged 100 years, at the residence of her daughter, 207 Diamond street. Mrs. Kelly was a native of county Derry, Ireland; she came to this country in 1853, and was the mother of eight children. Margaret Gasaway died on December 6, aged 106 years. She was a member of the Society of Friends, and came here from the Eastern Shore of Maryland, while she was quite young. Mary Winn died December, 23, aged nearly 101 years. She was a native of the old District of Northern Liberties, where she lived all her life, her husband, Jacob Winn, being one of the old-time night watchmen. She was the mother of ten children, the oldest survivor of whom is a daughter over 73 years old. Rachel Mahorn, widow of John Mahorn, died December 10, aged 100 years. She was born in Salem County, N. J. She left 3 children, 20 grandchildren, and 23 great-grandchildren. Daniel Webster, colored, died December 25, aged 105 years. He left 4 children, 13 grandchildren, and 13 great-grandchildren.

OBITUARY NOTICES.

PROF. JOHN W. DRAPER.

This eminent scientist died January 4th, in his seventy-first year. He was better known as a physicist than as a physician. He was born near Liverpool, England, but removed in early life to this country, and graduated in 1836, in the University of Pennsylvania, where he took the degree of M. D., with the rare distinction that his thesis was selected for publication by the medical faculty. A few weeks after his graduation he was appointed Professor of Chemistry, Natural Philosophy and Physiology, in the Hampden-Sidney College, Virginia. During his residence there he was much occupied with scientific investigations, many of his physiological discoveries being communicated to *The American Journal of Medical Science*. In 1839 he was called to the chair of Chemistry and Natural History in the academic department of the University of the city of New York, where, besides instruction in those branches, he delivered lectures to the advanced under graduates on physiology. In 1841 he was appointed Professor of Chemistry in the University Medical College, and in 1850 physiology was added to the chair of chemistry. Dr. Draper was long president both of the scientific and medical departments of the University.

He was the author of many literary works, reviews, etc.; a Treatise on the Forces which Produce the Organization of Plants (1844); a Textbook on Chemistry (1846); and another on Natural Philosophy (1847), which consists of excerpts from his courses of lectures; and of a treatise on Human Physiology (1856), many editions of which have been published. His "History of the Intellectual Development of Europe" appeared in 1852, and was almost immediately afterward republished in England and translated into French, German, Italian, Polish and Russian. It has always been an extremely popular work, and has gone through many editions in this country. In 1865, four lectures which he had delivered before the New York Historical Society were collected in a volume, under the title of "Thoughts on the Future Civil Policy of America;" and between 1867 and 1870 appeared, in three volumes, his "History of the American Civil War."

In some respects his most important work was "The Conflict between Science and Religion," which attracted great attention, it may be literally said, all over the world, and was translated into all the principal languages. It is the claim of Dr. Draper's friends that he is more widely read and appreciated than any other American scientist. Prof. Tyndall, in his famous address before the British Association at Belfast, quoted largely from Dr. Draper's works, and the kindly feeling between these two eminent men was great. Dr. Draper's last work was "Scientific Memoirs," published in 1878 containing a narrative of an extensive series of experiments made in the University of New York by its author, on various chemical and physical topics, between 1830 and 1870, chiefly in connection with light, radiant heat, and electricity.

—Dr. Edward Reynolds, the oldest physician in Boston, died, December 27th, at the age of 89 years. He was graduated from Harvard College in 1811, and was a classmate of the late Edward Everett, the late Chief Justice Dunkin, of South Carolina, and the late Chief Justice Lane, of Ohio.

MARRIAGES.

CRAWFORD—BARCLAY.—December 22d, 1881, at the home of the bride, by Rev. W. W. Moorhead, Dr. J. Shoenberger Crawford and Miss Isabella J., daughter of the late Th. J. Barclay, of Greensburg, Pa.

Just Out! New and Valuable Publications!

The Physician's Clinical Record and Case Book.

FOR 100 PATIENTS.

Neatly Bound in Cloth, with Pocket and Stencil Plate, Price $1.00.

This very convenient little book, adapted to be carried in the pocket, gives, in the briefest and neatest arrangement, the best forms of preserving the records of cases. A brass Stencil Plate accompanies each book, for rapidly sketching an outline of the body, in which may be marked, by shading, the seat of effusions, etc., or the size and position of organs, tumors, etc.

Several pages of Prefatory matter are given, presenting in the most succinct form a number of memoranda to refresh the memory of the practitioner, as: 1. Memoranda in Examining Patients; 2. Symptoms of Poisoning, etc.; 3. The Urine in Disease. Ruled Temperature Charts are added.

A MANUAL OF OPHTHALMIC PRACTICE,

BY HENRY S. SCHELL, M. D.,

Surgeon to the Wills Eye Hospital, Ophthalmic and Aural Surgeon to the Children's Hospital, etc.

With 53 Illustrations, Test Types, etc. Price, Cloth, $2.00.

This is a new and valuable work on ophthalmic practice, especially designed for the use of the general practitioner who desires a clear and compact manual of instruction in the management of diseases of the eye.

EXTRACT FROM THE PREFACE.

The object of the writer, in the following pages, has been to state briefly the generally accepted principles of Ophthalmology, and to describe those methods of treatment which he has become accustomed to rely upon from personal experience of their value.

CONTENTS.

CHAPTER I.—Anatomy and Physiology of the Eye. CHAPTER II.—Affections of the Eyelids. CHAPTER III.—Disorders of the Lachrymal Apparatus. CHAPTER IV.—Disorders of the Conjunctiva. CHAPTER V.—The Ophthalmoscope. CHAPTER VI.—Refraction and Accommodation and their Anomalies. CHAPTER VII.—Disorders of the Ocular Nerves and Muscles. CHAPTER VIII.—Diseases of the Cornea and Sclerotic. CHAPTER IX.—Diseases of the Iris, Choroid and Ciliary Body. CHAPTER X.—Diseases of the Crystalline Lens. CHAPTER XI.—Diseases of the Vitreous. CHAPTER XII.—Diseases of the Retina and Optic Nerve. CHAPTER XIII.—Disorders of the Eyeball. CHAPTER XIV.—Diseases of the Orbit.

PERICARDITIS.

BY AUSTIN FLINT, M.D.,

Professor of Principles and Practice of Medicine in the Bellevue Hospital Medical College, New York.

Gentlemen :—This patient presents a disease which is not so frequently seen in the hospital as are many other affections, namely, pericarditis, or inflammation of the investing membrane of the heart. I will read the history and make some comments upon the case.

John —, twenty-five years of age, a steward, a native of Ireland, admitted into the hospital on the 23d of this month. The family history is unimportant. He had never been ill, as long as he could remember; never had syphilis; is not accustomed to hard drinking; usually has drank one or two glasses of beer a day, with his meals; sometimes port wine. Three days before his admission he had a pain in his right foot, near the heel, and soon after noticed that the ankle and the foot were swollen. The swelling increased, the parts became red and hot, and extremely painful, especially on motion. Two days later the knee began to be affected with slight pain. At that time he thought he had some fever.

On his admission he complained of swelling and tenderness in his foot and some pain in the knee. The swelling was confined to the tarsal region, which felt hot to the touch and was very tender. There was no swelling of the knee, and the pain seemed to be more in the tendon than in the joint. The pulse was 90, full and soft, and the temperature 99° F.

Auscultation of the heart gave no evidence of any disease there. I wish to call your attention to the fact that the history gives no evidence that he ever before had acute rheumatism, while it does show that at the present time he has an attack of subacute articular rheumatism, limited to a few joints.

He was placed upon the following treatment: The salicylic mixture, half an ounce, containing salicylic acid, twenty-two and a half grains, in solution, every three hours; the bicarbonate of soda, half a drachm every three hours; lead and opium wash applied to the knee. I wish, here, to impress upon you, when using salicylic acid or salicylate of soda, which is now the general treatment of rheumatism, that it is important also to use the alkalies in sufficient quantity to render the urine as speedily as possible alkaline, with a view to diminishing the liability to the cardiac affection. Two days after his admission the swelling and pain in the foot were much diminished.

Now, the question arises, whether that treatment may not have prevented the further development of the rheumatic affection. We could probably answer that in the affirmative. On the third day after admission there was scarcely any pain in the foot, and last night there was no murmur to be heard in the cardiac region.

Now, this case furnishes occasion for impressing certain practical points. We shall see in a moment that we have evidence of endocarditis, that evidence consisting in the development of an endocardial murmur which we know did not exist before. Endocardial murmurs found after previous attacks of rheumatism, and other causes, are very common, and we cannot decide positively that endocarditis developed during the progress of a given attack of rheumatism, unless we were able to exclude its presence before.

On the 24th it is stated, that last night no murmur was to be heard over the præcordial region, but this morning there is a double friction murmur heard, with the greatest intensity at the left edge of the sternum, at its junction with the fourth costal cartilage. The sound is close to the ear, and is increased in intensity when the patient leans forward. A full respiration also increases the intensity, and raises the pitch.

Of course, the remarks which I have made about endocarditis do not apply to these symptoms; but it is fair to assume that this affection was also present, since, as I believe, it always accompanies rheumatic pericarditis.

In the afternoon, it is further stated, the murmurs had increased somewhat in intensity. The heart's action was then somewhat labored, and the first sound was indistinct. The murmur then became perceptible over both sides of the sternum. The area of superficial cardiac dullness was increased, the murmur became less intense, and pain disappeared. On the 27th, it is noted that the murmur was much diminished in intensity, the heart's action was still labored, the first sound very indistinct, and the apex beat diffuse. The percussion area of dullness was thought to be increased on a line between the nipples. On the 28th the murmur was still further diminished, the area of cardiac dullness increased, extending now about an inch to the right of the sternum, and to just beyond the left nipple on the same level. On the 29th the double murmur had disappeared, and a systolic murmur had occurred at the apex, but it was not transmitted.

This last statement contains evidence of endocarditis, or inflammation of the endocardium, and, indeed, is positive proof thereof, the absence of such a murmur having been determined beforehand. This murmur is produced by a certain amount of exudation within the left ventricle of the heart, there being no insufficiency of the mitral valve. It would not be strictly proper, therefore, to call it a mitral regurgitant murmur. The terms mitral systolic murmur without regurgitation, or an intra-ventricular murmur, distinguish it from a mitral regurgitant. As the term implies, it is heard with the first sound, and is located at the mitral valve, but it does not denote insufficiency of that valve.

Here, then, we have a case of rheumatic peri- and endo-carditis, occurring a few days after the commencement of a rheumatic affection. The rheumatic affection not presenting symptoms of sufficient intensity to be called acute, affecting only one, or at most two joints, and apparently readily and directly controlled by salicylate of soda. It occurs here to still more strongly impress upon your minds the importance of giving alkalies. Had this patient taken at the outset alkalies in sufficient quantity to render the urine alkaline, I think it is fair to say that the probability is he would not have had these murmurs. I will not say positively that he would not have had them, for the opinion of Mr. Fuller (who wrote many years ago), that rheumatic pericarditis never occurred as long as the urine was kept alkaline, was too strongly stated; we may say, however, that the liability to pericarditis is much diminished as long as the urine is kept alkaline. And here is another point which renders this case very instructive, namely, that while the salicylate of soda controlled the rheumatic affection, it did not prevent the affection of the heart, and since that remedy, salicylate of soda, has come into use, and has led, as it often has done, to the disuse of alkalies, cardiac affections have become much more common than before. I know, from personal observation, that we meet now with cardiac affections in rheumatism more frequently than we did when the alkaline treatment was relied upon, and the object of chief importance in the treatment of rheumatism is prevention of the cardiac affection, although it is, of course, desirable, if possible, to cut short the affection of the joints. But there is no such important consideration pertaining to the joint affection as there is to cardiac complications. Therefore, while it is perfectly proper, and indeed very important, to control the rheumatic affection by these remedies, we should not discontinue the use of the alkalies which reduce the liability to an affection of the heart. These points are so well illustrated in this case that I hope they will be borne in mind.

The pericarditis in this case is devoid of any apparent symptoms of gravity. It is one of those diseases which vary very much in different cases, as regards pain and other distressing symptoms, and symptoms of gravity. This patient is in bed, but had he been allowed his own will, he would have walked up to the amphitheatre. It is not proper for a patient with some pericardial effusion to take considerable exercise. That is an important practical point. He should take rest. I have known of at least two instances of sudden death, arising, apparently, from imprudent exercise during the presence of pericardial effusion.

Pain is sometimes exceedingly severe, having all the characteristics of pleuritic pains, and hence, when physicians relied wholly upon symp-

toms in diagnosis, cases of pericarditis were sometimes confounded with pleurisy. The pain is lancinating, sharp, of course, situated within the præcordium, and is increased on inspiration. In other cases there is little if any pain at all; not sufficient to call attention to the existence of any inflammatory symptoms at the pericardium. That is true, also, of other serious inflammations, as, for instance, acute pleurisy. Cases differ also with respect to the amount of the effusion; sometimes it is slight and inappreciable, in which event we distinguish the case as one of dry pericarditis. In other cases the effusion is moderate in quantity, in others considerable. In proportion to the amount of the effusion we have other symptoms dependent upon the effects of this, first upon the heart, and then upon adjacent organs. Of course, in proportion to the amount of the effusion the heart is compressed. It labors under mechanical disadvantages, hence, frequency or smallness of the pulse; hence, disturbance of respiration. Then, pressure by the enlarged pericardial sac upon adjacent organs sometimes occasions inconvenience. It presses upon the lung, and diminishes somewhat the lung capacity; it may press upon the œsophagus and thus interfere with deglutition.

In the vast majority of instances in which we meet with pericarditis, it occurs in connection with one of three affections, namely: first and most frequently, rheumatism—rheumatic pericarditis; next, perhaps, chronic Bright's disease; next, in connection with either pleurisy or pneumonia, affecting the left side. It is in these three pathological connections that we most frequently meet with pericarditis. The instances in which it occurs otherwise, including, of course, traumatic cases, are very few. It is very apt to be overlooked in connection with pleurisy and pneumonia, because we diagnose the presence of those diseases and think we have enough to account for the symptoms, and perhaps, omit to examine with reference to pericarditis.

As to the physical signs, I need not, I suppose, dwell upon the friction murmur. That is evidence of pericarditis, and also of pleurisy in the first stage. It is not, however, always found, even in the first stages of pleurisy, whereas in pericarditis I think I am safe in saying it is always present before much effusion has taken place. The movements of the two serous surfaces upon each other are such as to give rise to a murmur if the conditions for it be present, namely, a fibrinous exudation.

In order to be able at once to recognize the murmur, we must bear its characters in mind. Let us repeat them. In the first place, the friction murmur is almost invariably double; that is, it accompanies the two sounds of the heart, although it has not a fixed and uniform relation to them. They are, so to speak, in discord with the sounds of the heart, but there are two for each revolution. They convey to the mind the idea of friction. This in itself should not be relied upon in the diagnosis, for endocardial murmurs sometimes have that character. They seem to come from a superficial situation, right under the ear, or under the surface. They are increased in intensity when pressure is made over the præcordia with the ear or stethoscope. They are not conducted beyond the præcordia much, if at all, and are frequently heard only within a certain portion of the præcordia. These are characteristics of the pericardial friction murmur, as contrasted with an endocardial murmur. Endocardial murmurs, in order to be confounded with a pericardial friction murmur, must be double, since the pericardial murmur is double, and the only instance in which this error can be committed holds with relation to the aortic direct and the aortic regurgitant murmurs. The diagnosis can be made in that case by paying attention to the qualities of the endocardial murmurs, the conduction of the aortic direct up into the great vessels, etc.

After the effusion has been poured out into the pericardial sac, as in this case at present, the murmur disappears, and if we see the case for the first time at this stage, we have to depend upon other signs for our diagnosis. Removal of the heart from contact with the thoracic wall, by the presence of fluid in its investing membrane, alters the first sound, diminishes its intensity, and divests it of its booming quality. It becomes valvular, in that respect being like the second sound, and frequently being more feeble. This change is a very striking one, and was illustrated in the following case. Some years ago, when again about to commence my visiting service in the wards of the hospital, and while passing through, one of the assistants said, regarding a certain patient, that it was a case of rheumatism, a light attack; but, as a matter of curiosity, more than anything else, I put the stethoscope over his heart, and at once recognized the fact that the first sound was like the second, being valvular in quality. A further examination proved the presence of pericarditis with effusion, which had entirely escaped attention, because there was no pain or other symptoms pointing to it.

If the apex beat be above the normal position it is a diagnostic point in favor of pericarditis

with effusion. Sometimes it can only be felt by requiring the patient to lean forward, so that the apex may come in contact with the thoracic parietes. In this patient, the apex beat is in the fourth intercostal space, instead of in the fifth, which is indicative of some of the effusion still remaining within the pericardium. The presence of the effusion is further determined by percussion and auscultation, the former showing an increased area of dullness, and the latter an increased area over which there is absence of respiratory murmur. Increased area of dullness in the præcordial region, caused by pericardial effusion, is diagnosed from that caused by enlargement of the heart in this manner. In the latter the increased area of dullness extends more downward and to the left, while in the former the area of dullness is increased laterally, nearly equally on the two sides, and upward, and the triangular form of the area of dullness, corresponding with the form of the pericardium, is evident on percussion and auscultation. The apex beat, instead of being lowered, as in enlargement of the heart, is higher up than normal, in effusion into the pericardium.

The treatment of pericarditis varies considerably according to the amount of the effusion and the intensity of the inflammation, as denoted by the general and local symptoms. I have already spoken of the importance of quiet, which is an essential point in the treatment. If the patient suffer from a considerable amount of effusion, it is proper to treat it as we would effusion into the pleura, viz: we may give hydragogues; but always remember that this must not be carried to the extent of producing any considerable general debility. We may give diuretics. Sometimes blisters over the præcordia have a beneficial effect. I do not know that we can explain how it is done, but facts show that vesication of the skin lying over serous membranes aids in producing absorption of the contained effusion. I suppose a certain amount of benefit pertains to the application of the tincture of iodine externally. The patient, of course, is to be sustained by measures which do not excite the action of the heart, but which improve the constitutional power. If pain be a prominent symptom, of course that is to be relieved by the judicious use of opium in some form. We should continue the use of alkalies, and in that way, perhaps, keep the inflammation from increasing. A less quantity of the alkalies will be required to continue the urine alkaline than was required to produce alkalinity in the first place. These are the more salient points in the treatment of this affection.

Rheumatic pericarditis gives us a good ratio of recoveries. The prognosis, if there be no untoward circumstances, is favorable. Renal pericarditis, if we may so distinguish it, is quite otherwise. A very large majority of these cases prove fatal. Pericarditis occurring in connection with pleurisy and pneumonia, increases very much the gravity of those affections, and proves fatal in a considerable proportion of cases, although its presence does not warrant us in forming a fatal prognosis.

In the present case it is only important to keep the urine alkaline, and to prevent the patient from making those exertions which he seems inclined to do because he feels pretty well and has no local symptoms.

Asthma, Emphysema, Bronchitis.

The hospital record of the next case, gentlemen, is asthma, emphysema, and bronchitis, three affections which, as we have seen, are apt to be associated. The patient is a boy, thirteen years of age, a native of New York, who entered the hospital on the 28th of this month. His father had been subject to attacks of dyspnœa, coming on at night, for nearly twenty-eight years, and from that statement we may infer that his father suffered from asthma. This is one of the diseases into which heredity frequently enters as a cause. No other member of the family has been affected, although he has several brothers and sisters. Here we see an illustration of what we often see, that where heredity does enter into the causation of the disease, it may affect only one of a numerous family, the others escaping.

The personal history of the patient states that for more than seven years he has been subjected to attacks of difficult breathing. Here is an interesting point; that while asthma does commence early in life, especially in the inherited form, it is not common for it to commence as early as in this case. This boy was only six years of age when he began to have attacks of difficult breathing.

The attacks came on in the night, and generally lasted a part or all of the next day. At first they came on once a month, and he was sometimes free from them during three or four months. Two years ago he went to Kansas to live, and was there free from his trouble during several months. That part of our country, and more particularly Colorado, has been considered favorable to these affections. About eight months ago he returned to New York, and since then he has had an attack nearly every week. It is interesting to note this statement in connection with what was just previously stated.

He has had a cough as long as he can remember, and has had difficult breathing on very slight exertion.

Physical Examination.—On inspection, there is to be noticed a well marked deformity of the chest, the upper anterior portion bulging forward, the lower portion being retracted, particularly below the sternum. On inspiration the sternum rises vertically. The impulse of the heart is seen and felt in the epigastric region. On percussion in the infra-clavicular region the note is vesiculo-tympanitic. On auscultation over the upper part of the chest, most markedly in front, the inspiratory sound is weakened and short, the expiratory sound is prolonged and low pitched. There are a few mucous râles over the chest, varying in position, and also sonorous râles.

The patient was placed upon tonics and an emulsion of cod-liver oil, and should dyspnœa come on, he is given the fluid extract of quebracho, fifteen minims every hour, this being a new remedy, supposed to have a good influence upon dyspnœa occurring under different circumstances.

When we look at the boy's chest, we see that it has not exactly the deformity of emphysema, the barrel-shaped appearance which we have seen in other cases. This patient's breast looks more like what is commonly known as "chicken breast." The pulsation of the heart is seen in the epigastric region, as stated in the history. This might be due to emphysema affecting the left upper lobe, but on examination I find enlargement of the heart, principally of the right ventricle, with a loud pulmonary second sound, and this probably is the chief cause of the descent of the apex beat. I also hear sonorous râles, which are likely to be heard in cases of asthma, even at times when the patient is free from an attack. As the patient breathes deeply, we see the characteristic movements of emphysema; there is elevation of the whole chest, with some retraction of the lower part of the chest on inspiration. Vesiculo-tympanitic resonance is heard over both upper lobes, greater in degree, however, over the left than over the right lobe, which is the rule, with very few exceptions.

Since there is no valvular lesion present it is fair to attribute the enlargement of the right side of the heart to the presence of emphysema.

We have not time to consider the treatment of this case to day.

—The Danish Society for the Protection of Animals offers two prizes for the best essays on Vivisection. The question to be treated is the replacing, for medical experiments, of living animals by those freshly killed.

Communications.

SOME POINTS IN REGARD TO TROPHIC NERVE CELLS.

BY J. S. WIGHT, M.D.,

Professor of Surgery at the Long Island College Hospital.

Written for the Medical and Surgical Reporter.

(*Continued from page* 35.)

The third case reported on page 443, of the Surgical History of the War of the Rebellion, reads in substance as follows: Private W. S. L., 32 years of age, was wounded December 10th, 1864, by a conoidal ball, which entered the back on the left side, about three inches below the inferior angle of the scapula, fractured the eleventh and twelfth ribs, passed directly across the back, between the last dorsal and the first lumbar vertebræ, both of which it fractured, as also the eleventh and twelfth ribs on the right side, and lodged under the skin at a point almost corresponding to that of its entrance on the opposite side. The lower extremities were instantly paralyzed. The ball was readily extracted. There was slight hemorrhage, and considerable shock, with pain in the right lung. The urine was drawn off by the catheter, and the patient had an involuntary evacuation from the bowels. The bladder had to be emptied by the catheter, and the bowels evacuated themselves. There was some pleuro-pneumonia. About ten or twelve days before his death the tissues over the right trochanter, and for a short distance down the thigh, began to slough away. The sloughing continued until the trochanter was exposed, and commenced over the sacrum and left trochanter, although he did not suffer the least pain. At the autopsy it was found that the ball had passed directly through the cord, cutting it off.

Attention may now be drawn to some significant points in regard to this case:—

(1) There was no direct injury to the ganglia of the sympathetic. The disturbance to the sympathetic nerve cells must have been by the way of indirect irritation. The coördination and the correlation between certain spinal cells and certain sympathetic cells must have been completely destroyed. There may have been some spinal cells, that in their mutilated condition were still connected with the cells of the sympathetic, yet their influence on the cells of the lumbar ganglia would be in the line of irritation—in the nature of in-coördinate cell action.

(2) The lumbar enlargement of the cord was

severed, or cut off entirely, so as to cause complete paralysis of sensation and motion below the seat of the injury, and yet the involuntary motion to some extent still continued. At the same time it must be admitted that the cells of the severed end or part of the cord had some motor properties still left for a few days, so that there would be, to some extent, a coördination of spinal and ganglionic functions.

(3) The lumbar enlargement of the cord is said to be a trophic centre, that is, it is said that there are trophic cells in the anterior horns of gray matter, and that this is so we may admit, only we think it prudent to add that part of the trophic work is probably done by the cells of the lumbar ganglia, for it would be quite as competent to say that an injury to the spinal cells would irritate the co-related cells of the sympathetic ganglia, as it would be to say that an injury to the cells of the sympathetic ganglia would irritate the co-related cells of the spinal cord, and this would be more especially so in the present case, if it were not so in some other case, because of the nearness of the track of the ball to the tissues about the special elements of the sympathetic.

The necrosis of the tissues of certain parts of the body below the seat of the injury was caused by the injury in both of the above cases: (1) In the first case the injury was done to the lower sympathetic ganglion of the neck, and the implication of the cilio-spinal axis was no doubt indirect. (2) In the second case the injury was done to the lumbar enlargement of the cord, and the implication of the ganglia of the lumbar sympathetic was probably indirect. It is true, that we have no direct observation, as a matter of fact, in regard to the autopsy going to show that the cells of the lumbar sympathetic had suffered on account of the injury to cells of the cord, and yet it is highly probable that these cells did suffer, and that they had an influence in caus ing the necrosis of the sloughing tissues.

It is true, indeed, that nutritive activities take place in some organic forms in which there are no nerves; plants and some of the protozoa, have no nerves, and yet they develop and grow. *Nor do plants and certain protozoa have livers and kidneys;* but if they had such organs differentiated for them, why they certainly could not get along without these organs, and yet these organs are, in fact, made up of cells that have special and peculiar functions; and so are spinal cords and sympathetic ganglia made up of cells, which we call nerve cells. To be sure these cells have special processes, which we call nerves, but these processes are parts of the cells. To say that a protozoa, or a plant, can be nourished without nerves, has no weight in showing that the nerves of a highly organized being can be nourished without the intervention of nerve cells. To say that there are no nerve cells in the early life of the embryo, does not disprove any connection that exists between the adult nerve cells and the nutrition of certain other cells of the human body. Why, it ought rather to be said that a nerve cell is a special cell, doing special work, just as we know that a liver cell is a special cell doing special work. In fact, we know that in the nerve cell itself the most active nutritional changes are taking place, and that, in so far as nutrition is concerned, a nerve cell is very much like any other cell; in fact, the analogy, in this respect, of a nerve cell to a liver cell, to the cell of a protozoa, or to the cell of a plant, is very remarkable.

In this place it may be noted that the ganglion of the posterior spinal nerve root is a mass of cells, sending fibres to the cord and to various parts of the body; and that apparatus of the cell and its fibres has the functions of nutrition and conductivity; that is, a special cell carries on its nutrition much in the same way as any other cell, and has at the same time the power of conducting impressions. And this view leads us to a clearer conception of the functional powers and relations of the masses of nerve cells found in front of the cord: (1) The spinal cells have *white* roots, or fibres, which are distributed to various parts; some to the sympathetic ganglia; (2) the cells of the ganglia have *gray roots*, or fibres, which are distributed to the spinal cord in part. Hence, there are certain spinal cells and certain ganglionic cells that are intimately consociated in so far as their structure is concerned, and very probably have similar and consociated functions. Two things we surely know: (1) That some of the spinal cells are promoters of motion in the voluntary muscles; (2) that some of the ganglionic cells are promoters of motion in the involuntary muscles. We also surely know that injuries to some of the spinal cells and some of the ganglionic cells disturb the nutrition of some of the cells in certain parts of the body. And the cases above cited show that this is so, and aid us in comprehending the functions of the spinal nerve cells and the sympathetic nerve cells. And the outcome of this view is, that there are certain nerve cells in the spinal cord and certain nerve cells in the sympathetic ganglia that are promoters of the movements of nutrition.

In a given case, if we suppose a motor nerve cell to be paralyzed, the muscle cells to which

its axis cylinder goes will also be paralyzed. And if in a given case it is found that certain cells that are not muscle cells are necrosed or degenerated, it must follow, according to the view we have advanced, that certain nerve cells are irritated, inflamed and destroyed, and these nerve cells are called *trophic*, because they have a special influence on the processes of nutrition.

In this place let me say that two views in regard to *trophic* nerve cells have been brought forward: (1) It is supposed by some that the *trophic* nerve cells exist in the spinal cord, notably in the medulla oblongata, the cilio-spinal axis, and the genito-urinary enlargement. (2) It is supposed by others that the *trophic* nerve cells exist in the sympathetic ganglia. Let me add, that each of these views is correct, to some extent, and that one does not exclude the other, for the truth includes, as it were, both views; that is, the *trophic* nerve cells exist in both the spinal cord and the sympathetic ganglia. And the two sets of cells, *in* and *in front of* the cord, are *co-related* in their structure, and *coördinated* in their trophic functions, as well as the motor nerve cells of the cord and the ganglia are *co-related* in their structure and *coördinated* in their special functions.

It is possible to support this view by a consideration of the *semilunar ganglia*. Which is the most important, the special function of the liver, its simple function of nutrition, or the motor function of the fibres of its blood vessels? Any part of the mechanism of the liver is important no doubt, but why should a considerable part of the semilunar ganglia and the hepatic plexus be set apart for the hepatic blood vessels only? It seems to me that the blood vessels of the liver, as compared with other organs of the body, ought not to need the cells of a very considerable part of the semilunar ganglia, and the extensive hepatic plexus, for the contractile work that they are called upon to perform. But it seems to me rather, that some of the cells of the semilunar ganglia are especially engaged in aiding the liver cells to carry out their special functions. In other words, there are ganglion cells that have special trophic functions. Of course, the influence of other parts of the nervous system on the functions of the liver, are not to be overlooked. In this connection, it may be mentioned that the disturbing influence of diseased renal ganglia on the function of the kidney has recently been pointed out by Da Costa and Longstreth; and the meaning of this disturbance is, that the renal ganglia contain *trophic* nerve cells. But these trophic cells are not in the spinal cord, nor in the pre-vertebral ganglia of the sympathetic; they are in abdominal ganglia differentiated from the pre-vertebral ganglia; and if these nerve cells are *trophic*, as they no doubt are, why should not some of the cells of the pre-vertebral ganglia be also *trophic*?

By the term *trophic*, it is not intended to convey the idea that the visceral ganglion cells are the sole agents in the conduct of nutrition. The meaning of the facts is this: the nerve cells of the visceral ganglia, and the special cells that are acting on, and absorbing, and transmitting into the blood vessels the elements of food, are differentiated and are co-related, and they are coördinated in the work of the primary steps of nutrition. There is, as it were, a kind of cell co-partnership for the attainment of a special object; each co-partner performs his own work, and the entire work could not be performed by the ganglion cell, or by the liver cell. In this sense, a ganglion cell is a *trophic* cell, and a liver cell is also a *trophic* cell. And it would be proper to note, that the renal cells are concerned in part of the work of the last steps of nutrition, and that these cells are coördinated with the cells of the renal ganglia; and if nerve cells are associated in the first steps and the last steps of the processes of nutrition, then the question arises: Are not nerve cells associated with the intermediate steps of the processes of nutrition? that is to say, are not those intimate changes that occur in the general structure of the various cells of the body associated with the nerve cells? My reasoning tends toward this conclusion. In fact, there is a point of evidence that appears to have great weight in determining the question, and that point relates to the cornea.

If we admit that the cornea has no vessels, the capillaries terminating in loops at its circumference, and that it is composed of anastomosing fusiform cells, between which are tubular interstices, and that it is abundantly supplied with nerves, coming probably from the *lenticular ganglion*—we may then, in the most reasonable manner, say, that there is no need of motor nerves to act on the muscular fibres of a blood vessel in the cornea, because there is no such blood vessel. But in all reasonable probability we may say that the nerves which enter the cornea are in some way co-related to corneal fusiform cells. And it is quite a remarkable fact that the blood vessels which surround the cornea, that is, their muscular fibres, are supplied with nerves from the same source as the cornea itself—as we have said—the lenticular ganglion. Now, I think it can be understood, that, as the vascular loops

around the cornea supply the nutrient material in connection with their special nerves, the coördinated nerves going to the fusiform cells of the cornea carry from the cells of the lenticular ganglion an influence having much to do with the functions of the cornea, and therefore, with its nutrition, in other words, the fusiform cells of the cornea have nerves that come from *trophic* nerve cells.

A special function of the cornea is the transmission of light and the nutrition of the corneal cells, and hence their molecular construction must be such as to keep up this special function. But as a matter of fact, some animals that for some generations have been without light are destitute of the special corneal structure, showing that special function, or use, in some way modifies the nutrition, and no doubt also modifies the nerve supply, as we may see by comparing the corneal nerves with other superficial and special nerves. And so in whatever reasonable way we look at the corneal nerves—with their cells—and the fusiform corneal cells, we are drawn to the conclusion that there is a coördination of work in the field of nutrition, between special cells.

The corneal cells were differentiated to let the waves of light pass through them, and some of the cells of the lenticular ganglion were differentiated to aid the corneal cells in keeping up a molecular structure that will not impede the light waves as they pass to the retina. Well, the cornea is a kind of connective tissue, which is, in a general way, part of the connective tissue of the body, and it has been found that nerve fibres go to or near the cells of the connective tissue, and as the connective tissue, as it were, performs *frame work*, its function being mechanical, somewhat different from the function of the cornea, where there is molecular mechanism, and as the cells of the connective tissue have not the special mobility of muscle cells, having no need of special motor nerve fibres, it is very reasonable to suppose that the nerve fibres going to these cells coöperate in the work of nutrition, and that the nerve cells from which these fibres come are *trophic*.

(*To be Continued.*)

TEMPORARY GLYCOSURIA, PRODUCED APPARENTLY BY ENFORCED SEXUAL CONTINENCE.

Paper read before the Medical Society of D. C.,

BY H. C. YARROW, M.D.,
Of Washington, D. C.

I desire to call the attention of the Society to the history of a case which, in my opinion, is interesting and somewhat curious. A short time since I was consulted by a male patient, a little over middle age, who complained of a constant desire to urinate; he had pain in the back part of the head, in the lumbar region, and feared that his kidneys were affected. These symptoms had developed within a few days anterior to his visit to me. I requested and obtained a specimen of morning urine, which was of high specific gravity, and which, upon being tested with Fehling's solution recently prepared, showed undoubted presence of sugar. To corroborate my own examination, a sample of the same urine was submitted to Dr. Mew, the chemist of the Army Medical Museum, whose analysis produced similar results. The patient was put upon ammonia bromide combined with fluid extract of jaborandi, and counter-irritating applications were made to the nuchæ and lumbar regions. This treatment was persisted in for nearly a week, the urine being tested for sugar every day; in eight days it had entirely disappeared, and up to the present time is still absent. To get at the history of the case, the patient was subjected to a rigid examination, and was finally induced to make a clean breast of the whole affair, which seemed to me to account for the symptoms related.

A few months since he contracted a friendship for a lady, which gradually increased to something warmer, and finally certain liberties were permitted and taken; but having been placed upon his honor not to go too far, my patient was kept in a state of constant erythism, without being able to gratify the necessities of his ardent nature. In the fullness of his confidence, he informed me that he had endeavored, upon several occasions, to cool his passion with other women, but was unable to succeed. His condition, as evidenced by the urinary trouble, became at length alarming, and induced him to seek professional assistance. It is my firm belief that the history, as related, will account for the sugar in his urine, for we are told by a number of writers that temporary glycosuria may be produced by a number of causes. For instance, T. Lauder Brunton, in Reynolds' System of Medicine, says that sugar in the urine is produced sometimes by violent and depressing emotions; some cases seem to arise from severe bodily exertion and sexual excesses. Roberts states that violent mental emotions may produce it, and this opinion is shared by Bartholow and others. Per contra, in discussing the case, it should not be forgotten that, according to Lionel Beale, occasionally de-

cided traces of sugar may be detected in the urine of persons who are not suffering from any particular symptom. It may be excreted for days, or even for a few weeks at a time, in small proportions. It occasionally happens that after abstinence from food for some hours, a meal consisting entirely of starchy matters will cause sugar to appear in the urine, and if a healthy person under these circumstances takes a quantity of cane sugar, a temporary diabetic condition will almost certainly be induced. We should also remember that the inhalation of chloroform has produced temporary glycosuria, and injuries to the brain have sometimes a like effect. It is not necessary to repeat here the many experiments which have been made upon animals to prove this fact. I should not omit to state that toward the close of my patient's attack nature relieved the distended seminal vesicles, and the next day no sugar was found in the urine. An examination was this day made (March 24th) of the urine of the patient spoken of, and not a trace of sugar discovered.

I submit this case to the Society, trusting that from the large experience of my professional brethren some additional light may be thrown upon the subject of temporary glycosuria, and if my conclusions are erroneous I may be set aright.

Hospital Reports.

WEST PENNSYLVANIA HOSPITAL, PITTSBURGH, PA.

Reported for the Medical and Surgical Reporter, by T. L. Hazzard, M.D., Resident Physician.

There have been, during the last seven years, nine cases of

Abscess of the Liver

in this hospital. This is such an unusual number for this latitude that a brief history of them may be interesting to the general reader, or prove useful to those interested in statistics:—

Case 1.—John R., aged thirty-six, born in Pennsylvania; married; temperate; admitted April 3d, 1874. Has had frequent attacks of intermittent fever; was confined several months in prison during the Rebellion; history previous to the war good; has not been in good health since.

Symptoms: Headache; diarrhœa; tenderness in right iliac fossa; emaciated; no appetite; temperature 102°; was supposed to have typhoid fever. Condition remained the same until the 9th, when he had a rigor, followed by a rise in temperature, 104°. Began to show signs of peritonitis over the right side, extending from the iliac fossa to the border of the ribs, with the accompanying symptoms. Four days after peritonitis had disappeared, under treatment. Upon the 16th he sat up and seemed to be recovering. Had profuse night sweats, but no pain until the 20th, when the pain grew intense, and vomiting began, and diarrhœa returned. Patient grew weaker every day, until June 7th, when he died. Treatment supportive, with blisters and absorbents.

Autopsy.—Liver completely filled with small abscesses, except in lobus spigelia. Evidences of caseous degeneration and absorption showed some of the abscesses to be of long standing. Bowels showed numerous ulcerations from long standing dysenteric diarrhœa. Other organs normal.

Case 2.—Thomas McK., aged thirty-two; Ireland; puddler. Admitted July 16th, 1874. History not clear; suffering acute pain in right hypochondriac region; liver dullness extended from four inches below the ribs upward to the third rib, and from the median line in front to the same line at back. Had been suffering for three weeks before admission.

July 18th. Suffered great pain; dyspnœa; tumor increasing upward.

July 19th. Died.

Autopsy.—Right lobe of liver was one huge abscess. The pus had perforated the diaphragm, and the right pleural cavity was filled with thick, fetid pus. The lung was compressed and the heart pushed to the left.

From the nature of his vocation, that of iron puddler, the abscess was probably of traumatic origin, as no other cause is assigned.

Case 3.—Charles M., aged thirty-four; Englishman; puddler; man of good habits and good health. Admitted Nov. 19th, 1875. Eleven weeks before began to have pains in region of liver, shooting into his right shoulder. At the same time he had rigors, followed by profuse perspiration. These symptoms occurred at irregular intervals, the pain finally becoming so severe that he sought relief in the Homœopathic hospital. Remained there for eight weeks, when he was admitted to this hospital. Could rest in bed only in sitting posture; breathed with great difficulty; emaciated and slightly jaundiced; abdomen greatly distended; bowels constipated; fullness of right side until the intercostal spaces were obliterated; severe pain over liver; dullness increased. The seat of the most severe pain was under the sternum.

Diagnosis of abscess made and exploring needle introduced. A few drops of blood flowed out, but no pus.

December 13th. Has had a month of comparative ease. Has taken stimulants, with morphia, to relieve pain. To day suffers great pain over liver. Pain extends over abdomen, and general peritonitis sets in.

December 17th. Condition grew steadily worse. Died.

Autopsy.—Peritoneum greatly inflamed. Cavity filled with sero-purulent fluid, and flakes of lymph. Strongly adherent in the median line. A large abscess was found in the upper and posterior part of the right lobe. It was filled with a yellow, thick pus. The right suprarenal capsule was destroyed, and the kidney formed a part of the abscess wall. Other viscera apparently normal.

Case 4.—Richard H., aged 40; born in England; laborer in rolling mill; intemperate. Admitted December 22d, 1875. Has history of bad health, with pain in bowels, diarrhœa and headache. Was treated for inflammation of bowels. Has thin, clay-colored stools; several daily. They are exceedingly offensive, and sometimes contain blood.

January 11th. Had œdema of right leg and thigh, and left leg to the knee. Right abdominal and thoracic parietes as high as nipple. Hepatic dullness increasing upward; is as high as the nipple, and extends downward into the iliac fossa. Urine voided in small quantities, and deposits lithates; contains albumen. Patient lies with head and shoulders elevated, and knees drawn up. Pulse thin and wiry. Extremities cold and clammy. Suffers no pain.

Jan. 20. Had delirium. Temp. 103. Died the next day.

Autopsy.—Abdominal cavity contained four and one-half quarts of sero-purulent fluid. Colon contracted, and filled with dysenteric ulcerations. The liver contained two cavities, the smaller one having evacuated its contents into the colon. There was a deposit of tubercle in the apex of the left lung. The left pleural cavity contained about six ounces of serum. The right pleural cavity contained about eight ounces of fluid, and there were adhesions in both. There were blood clots in the pericardium.

Case 5.—Francisco B., an Italian, aged thirty-five; single; spoke but little English. Had been having pains at irregular intervals, in hepatic region, for three months. Examination showed bulging of the ribs in the left hypochondriac region, and a fullness in the epigastrium, where the most severe pain was. The dullness was normal on the right side, but extended below the ribs for some distance on the left. The impulse of the heart was communicated through the abscess, and could be felt and seen below the ribs on the left side. He had profuse sweats. Continued about the same until December 30th, when he was attacked by severe pain, diarrhœa and vomiting. He gradually grew worse until his death, January 3d. The highest temperature reached was 102°.

Post-mortem showed a large abscess in the left lobe, which had destroyed the entire lobe. Right lobe apparently normal. The heart and left lung were pushed above the third rib by the arching of the diaphragm. All other viscera normal.

Case 6.—Chas. McI., Canadian, aged twenty; teamster; temperate. In May, 1880, was drawing logs from the river, when he fell upon the end of one, striking upon his right side; was obliged to go to bed for a week; resumed work again, but was obliged, by pain in hepatic region, to leave off hard work. Had pain in right shoulder and side. Has never been in a warm climate, never had dysentery, or suppurating wound. Admitted to hospital in November, 1881. At this time there was pain in side and shoulder, cough, abdomen somewhat distended, and liver dullness extending high into right chest cavity. Diagnosis of pneumonia made, but soon changed for abscess of liver. Continued, sometimes better, sometimes worse, until January 2d. At this time the dullness extended from the right nipple well down into the inguinal region, and over as far as the umbilicus. Deep fluctuation detected near the ensiform cartilage. An aspirating needle was introduced by Dr. W. J. Asdall, four inches below the nipple, in the mammary line, drawing off sixty-four ounces of purulent, sanguineous fluid. Patient experienced great relief of all the symptoms. A flexible catheter was introduced and retained in place. The cavity was washed daily with carbolized water, 1 to 40, and the patient given tonics and nourishing diet. Improved rapidly and steadily until April 1st, when he had severe diarrhœa, and his health began to break down rapidly; appetite became poor until, from exhaustion, he died, May 28th.

Post-mortem showed three-fourths of the right lobe occupied by the cavity. The pus had perforated the diaphragm and broken into the pleural cavity, where a sack had been formed by pleuritic adhesions. The right kidney was adherent to liver; lungs and heart normal, except right lung, which was very much contracted by pressure.

Case 7.—James C., born in Louisville, Ky.; aged nineteen; river man. Has lived all of his life in Louisville. Has been further south for months at a time. From time to time he has noticed little swellings over his liver, which would make him a little sick, but, when painted with iodine, disappeared in a few days or a week. Entered the hospital with the usual symptoms, May 28th, 1881. The dullness extended from the third right rib to below the lower border of the last, and on the left was continuous with the spleen dullness.

June 2d. Fluctuation being detected, the tumor was tapped by aspiration, between the seventh and eighth ribs posteriorly, and twenty ounces of sanguineous pus removed. The abscess was not entirely emptied, and a drainage tube introduced allowed of the slow evacuation of pus as it accumulated. A local peritonitis followed, but was easily controlled, and great relief experienced. Five days afterward there were all of the symptoms of collapse. The pulse became feeble; temperature, 95; skin cold and clammy. Active stimulation restored him. In a few days afterward all bad symptoms had disappeared. Decided to make an opening lower down, which was done by free incision with the knife; evacuated about two pints of yellow pus; a curved trocar and canula were introduced, and nearly two quarts more flowed out. Emaciation was rapid from this time, but the relief was great. He was seized with secondary pneumonia, and died June 22d, having been in the hospital not quite one month.

Post-mortem showed the right lobe entirely taken up by a large cavity; there were numerous cicatrices in liver, which had doubtless been small cavities; the other viscera apparently normal.

Case 8.—C. P., aged 47; temperate; born in Pennsylvania; had never been in the south; never had dysentery or suppurating wound. When brought to the hospital was suffering with great pain in hepatic region; slight jaundice. He was so bent over, that it was impossible for him to as-

sume the upright position; liver dullness extensive; dyspnœa. Diagnosed pneumonia; afterward the abscess pointed in the back on the right side. Diagnosis changed to lumbar abscess; then again to abscess of liver; was opened by bistoury, and sanguineous pus to the amount of two pints discharged. Debris of liver tissue found in pus. (Notes are here wanting until three weeks afterward, when patient was discharged cured.)

Case 9.—L. M., aged 46; intemperate; iron puddler. Three weeks before entering hospital he began to feel bad; vomited, and had severe pain in right side; has had vomiting spells once daily, at least, ever since, and has had chronic diarrhœa. Entered hospital June 1. Upon examination, a tumor the size of a cocoanut was seen upon the left side. There was fluctuation. Tumor very painful, as, indeed, was the entire abdomen. Dyspnœa, continuous vomiting and purging.

June 2d. Patient died. The liver was found to contain six cavities, from the size of a cocoanut to the size of a walnut. The large cavity mentioned above had bursted during the night, and pus was in abdominal cavity. The pus in the several cavities was green, or yellow, or reddish yellow. Extensive peritonitis; ulceration of bowels and stomach. Other viscera normal.

The treatment in all of these cases was supportive, and the various symptoms were treated as they would arise. It will be seen that the causes can reasonably be traced to ulceration of bowels in these cases. Traumatic causes in two; living in tropics (?) two; no cause, two. Two only were multiple, the rest being single abscesses.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF WILLIAM GOODELL, M.D.,

Professor of Clinical Gynecology in the University of Pennsylvania.

Reported by Wm. H. Morrison, M.D.

On Monday, Nov. 14th, 1881, Dr. William Goodell performed

Double Ovariotomy,

at the Hospital of the University of Pennsylvania. The operation was performed in a private room of the hospital, in the presence of one section of the graduating class of the medical department of the University. Previous to the admission of the class, the atmosphere of the room was saturated with a spray of carbolized water, the patient etherized, placed on the operating table, and a piece of rubber cloth, about one yard square, having at its centre an oblong hole eight inches in its longest diameter, was secured to the abdomen by means of lead plaster spread around the circumference of the opening. The object of this was to protect the clothing of the patient from the discharges. This it did perfectly.

Dr. Goodell was assisted by Drs. B. F. Baer, W. L. Taylor and Palmer. Ether was used as an anæsthetic, and the antiseptic method was adopted in all its details, the operator and his assistants carefully washing their hands in carbolized water previous to the operation, and also several times during its performance, the sponges being thoroughly and frequently washed in a carbolized solution, the instruments being kept in a 2.5 per cent. solution of carbolic acid, and a spray of the same strength, from a powerful steam atomizer, being kept directed on the parts during the operation and the dressing of the wound.

The Doctor premised the operation with the following remarks: "Mrs. J. S. C., aged thirty-six years; married; two children, aged respectively, fifteen years and eleven years. The catamenia are regular and free, accompanied by bearing down pains. She came to consult me on October 7th, 1880, on account of various uterine symptoms, and a tumor, which she had discovered only six months previously.

"The womb measured 3.5 inches, and lay to the left, and so high up that the tip of the sound could be felt in the left groin. To the right of the womb and posterior to it was an elastic tumor as large the fœtal head, conveying the sensation of fluid. It seemed very closely adherent to the womb, and every motion communicated to it affected also the womb.

"The diagnosis which I made at that time was cystic degeneration of the right ovary, but the tumor formed so slowly that after a year it had hardly reached the navel, and I was disposed, therefore, to consider it a cyst of the broad ligament. It gave her, however, far more pain and uneasiness than is usually produced by either ovarian or parovarian cysts.

"On Oct. 5th, 1881, I tried to empty the cyst by an aspirator, but succeeded in removing only half a pint of thick, stringy, colloid fluid. The diagnosis was, therefore, narrowed down to colloid multilocular cyst of the right ovary.

"I shall now proceed with the operation, and I hope that no one will speak to me or ask me any questions during the operation, nor shall I talk much, as one needs all his wits about him in performing this operation."

The abdomen having been washed with the carbolized solution, an incision, beginning one inch below the umbilicus and extending downward four inches, was made. The skin, superficial fascia and muscles were carefully cut through. The transversalis fascia then appeared. This was cut on the director, and the peritoneum exposed. All bleeding vessels were now secured by pressure-forceps, having a catch. The peritoneum was hooked up with a tenaculum and divided. The cyst then appeared, the doctor remarking that "whenever you see this blue colored cyst, it is almost invariably a cyst of the ovary. In my operations, when this blue color was present, it has always been a cyst of the ovary. As I have said, my diagnosis is that this is a cyst of the right ovary, but it may be of the left, for I have been caught on that point."

Wells' trocar was then introduced, but only a small quantity of thick, yellowish fluid escaped. By a little manipulation, enough fluid was removed to allow of the opening into the cyst to be drawn through the wound in the abdomen. It was then enlarged and the hand passed into the cyst, breaking up some of the smaller ones. After

this, the tumor was drawn out as far as possible, and each cyst punctured as it appeared. This allowed the tumor to be drawn through the abdominal incision. Two flat sponges were then passed in on each side of the abdomen, to prevent the air and discharge from reaching the peritoneum. The pedicle was then secured temporarily by Dawson's clamp and the tumor removed. A needle, armed with a double thread, was passed through the pedicle, and the pedicle tied in two sections, the Doctor remarking, "for tying this, I use the finest silk thread (carbolized) compatible with strength.

"This case has been a very easy operation. There were very few adhesions. Last Saturday I performed this operation thirty miles on the other side of Pittsburg, and removed a solid tumor of the ovary, which is a very rare form of growth. I am going to return this pedicle to the abdominal cavity. You might ask, 'Will not the distal end slough?' No, it will not. This ligature has cut deeply into the stump. The thread has entirely disappeared, and the parts on each side of the ligature are in contact. Plasma will at once be thrown out, and within twenty-four hours blood vessels will pass from one side to the other. The remains of the pedicle will also contract adhesions to the surrounding parts and in this manner receive nourishment.

"The case that I operated on a week ago to-day, from which we removed both ovaries and two fibroid tumors, is doing very well. I shall now examine the other ovary (the left)." This ovary was also found to be diseased, and was removed, with the fimbriated portion of the Fallopian tube. A sponge was then placed in Douglass' pouch, to see if there was any oozing of blood. The doctor had the sponges carefully counted several times, to make sure that they were all accounted for. "It is very important," he remarked, "to count the sponges, for almost every ovariotomist has left sponges in the abdomen." Two sponges were left in the abdomen while the external stitches were being passed. These consisted of carbolized silk threads, armed with a needle at each end; they were passed from within outward, and included all the tissues. "I include the peritoneum because it unites with great quickness; it will have united in twenty-four hours: so that if there is any pus formed in the upper layers of the wound, it cannot get into the peritoneal cavity." The external stitches having been passed, the sponges left in the cavity were removed, and found to contain no blood. The sponges and the dressing forceps were again counted, and the number having been found to be correct, the external incision was closed.

"Spencer Wells performed an ovariotomy one afternoon (his usual time for operating), and in the evening he had to come again to the hospital, because the nurse, in cleaning the instruments, had found that one pair of forceps was missing. Mr. Wells had to open the wound and fish for the forceps before he found them. You see that we cannot be too careful in counting the instruments and sponges. I know of one instance, where a gentleman, while breaking up adhesions, was on the point of losing a large seal ring, and would have lost it in a moment more, if his attention had not been called to it by a bystander."

A piece of salicylized cotton was then moistened in the spray and placed over the wound, a pad of raw cotton, secured by half a dozen adhesive straps, was used to fill up the hollow in the abdomen, and the dressing was finished with a flannel binder.

"What will her diet consist of? As she has been starved to day we shall not be troubled with vomiting. She will receive nothing to eat for forty-eight hours. If she is thirsty, she will receive a little hot water—sips of very hot water—and if necessary a little ice, but the hot water is preferable to the ice. After that time we shall begin to give her a little milk. Immediately after the operation, an opium suppository will be slipped into the bowel. Enough opium will be given to relieve what pain she may have.

"A word in regard to the spray. Some ovariotomists are giving up the use of the spray, but I am not ready to give it up, especially when I have you gentlemen present, for you have been around the dissecting room and the wards of hospitals. I should not have ventured to have you present, even with the spray, if I had not, when in London this summer, seen the operation performed successfully in the presence of a large number of persons."

The patient was then put to bed and cans of hot water placed along the body.

The time occupied in performing the operation was forty minutes. She recovered promptly and without any bad symptom.

Editorial Department.

Periscope.

Subcutaneous Ligature in Varicocele and Varix.

Mr. John Duncan says, in the *British Medical Journal*:—

The treatment of varicocele always presents a certain difficulty to the surgeon. This disease is not dangerous to life, nor does it seriously interfere with ordinary functions and avocations; but it is a source of harassing if not severe pain, is a matter of solicitude to the patient, and in some cases leads to wasting of the testicle. The former considerations have led some to recommend palliation by suspension, the vein-truss, and the cold douche; while the immense number of operative measures which have been devised, and which are not devoid of danger, bear witness to the importance of the latter. In the subcutaneous ligature by catgut we have a means of meeting the difficulty. It is singularly easy of application, free from risk, and very certain in its results. The mode of applying it is as follows: The veins are carefully separated by the fingers

from the artery and vas deferens, and a needle armed with catgut is thrust through at the point of separation; it is again introduced at the orifice of emergence, made to pass between the veins and the skin, and finally brought out at the original entrance. The two ends are then firmly knotted with as much force as strong catgut will bear, and cut short. By traction on the loose skin of the scrotum, the knot is made entirely to disappear, and the punctures are covered with salicylic wool saturated with collodion. The same manœuvre is repeated at a distance of an inch or a little more. I have now performed the little operation six times with complete success. In two cases, three ligatures were applied; but, in the others, to tie the vein at two points has been found sufficient. The effect is the formation of a hard lump of coagulum between the ligatures, at first slightly tender, but which soon becomes perfectly callous. I have just examined a patient on whom I operated more than a year ago. He gives me the most satisfactory assurances of complete relief. A small, hard nodule is still to be felt; the testicle is a little larger than its fellow; and the superficial scrotal veins are somewhat distended. But he feels no inconvenience, and has given up the suspensory bandage which he wore before the operation. The other cases have turned out equally well, and in one of them there has also been a year's probation. In two of them there had been previously some wasting of the testicle; but I hear that this has not as yet progressed further.

The success of the treatment of varicocele by this means induced me to apply it also in varix of the leg. So long as a varicose vein is not a source of inconvenience or danger to the patient, the general opinion seems to be that the use of the elastic stocking is all that is necessary. If that be not effectual as a cure, at least it prevents further deterioration. I should be inclined to say that, even in advanced cases, the stocking ought first to be tried; but when solid œdema and eczema and ulceration cannot thus be kept in check, or perpetually recur, some more radical measure becomes plainly desirable. There are also cases in which a limited portion of a single vein is greatly distended, and in which, although giving rise to little inconvenience at the time, it is, from its high situation, difficult to control by pressure, and likely, therefore, to spread and increase. In such cases, if a radical remedy be simple and safe, it ought to be applied. Some have objected to all operations involving the obliteration of a vein, that there is a likelihood of others becoming varicose; and that the deep-seated varicosity thus induced is apt to be painful. But I am sure that must be rare. Undoubtedly the same causes which were originally at work may be allowed to continue their action in other veins, through want of care; but it is not consistent with experience that, when one vein or set of veins is obliterated others become varicose. On the contrary, veins on which backward pressure is thrown tend to varicosity; but parallel channels only enlarge and dilate. There is a long step between varicosity and simple dilatation. Large portions, for example, of the femoral vein often become obstructed in fever and other blood diseases. The leg may afterward remain permanently enlarged; but the veins are little more prone to varicosity than in the sound limb. But even if such were the case, a problematical future evil would not justify abstention from what otherwise is beneficial; and the improvement that follows obliteration of a varicose vein is rapid and distinct.

The operation is performed precisely as for varicocele. The needle is passed first under the vein, and then between the vein and the skin, entering and emerging by the same punctures. It is not so easy to draw the skin over the knot after ligating as in varicocele; and this will be facilitated by slightly enlarging the puncture by means of a tenotomy knife. When, as is sometimes the case, the limb is swollen and brawny, and the veins run, as it were, in gutters cut out of the solid œdema, the difficulty of operating is considerably increased. In such cases I have, as a preliminary, kept the patient at rest, and applied the India-rubber bandage for a few days. It is always of advantage, during the operation, to have the limb gently constricted by a bandage above the point of ligature, in order that the veins may be distended with blood, which afterwards coagulates.

The Treatment of Hay Asthma.

The following summary of treatment is given by Dr. J. C. Thorowgood, in the *Lancet*, July 16th:—

Anti-congestive Remedies.—Of these one of the best is ammonia, used in the form of ordinary Preston salts (a mixture of the neutral carbonate of ammonia with oils of cloves and lavender), or as ammoniacal vapor, inhaled for a few minutes from a mixture of twenty drops of the liquor ammoniæ (B. P.) in a pint of water at 80° F. Ten drops of spirit of camphor and three to five of eucalyptus oil may often be advantageously added to this inhalation. The ammoniacal vapor slowly inhaled by the mouth and exhaled through the nostrils acts as a stimulant and promotes the mucous flux, by means of which the congested vessels are already commencing to relieve themselves. The action of the ammonia permanently tends to diminish hyperæmia of the mucous membrane, and in this respect ammonia differs markedly from other stimulating inhalations, which give only temporary relief. Properly managed inhalation of chloride of ammonium is useful in cases where hyperæmia of mucous surfaces is very marked and chronic.

With a view to destroying the pollen granules in the nasal passages, drawing up into the nostrils, or inhaling as spray, a solution of sulphate of quinine is decidedly useful. Ten grains of the sulphate may be dissolved in one pint of distilled water and this solution snuffed up into the nostrils—a method preferable to the employment of the solution by the nasal douche, for more than one reason.

Last summer I tried, for the relief of the throat irritation of summer catarrh, lozenges containing one grain of salicylate of quinine in each lozenge. The salicylate is supposed to act as a germicide, and destroy the vitality of any inhaled pollen germs. Carbolic acid vapor is very useful.

Iodine vapor I have also tried as an inhalation, but never saw any benefit come of its employment. A liniment of equal parts of chloroform, simple camphor liniment, and eucalyptus oil rubbed well round the throat relieves irritation; the smell, too, of the antiseptic eucalyptus oil is, at the same time, not without good effect. When the congestion and catarrh have extended downward to the air-tubes, so as to cause bronchial spasm and regular attacks of hay asthma, then few remedies appear to surpass arsenic, and this may be employed by vapor or by the mouth. As a remedy for asthma arsenious acid has long been used by the Chinese.

I have had opportunity of trying nitrated paper cigarettes, after the formula given by Trousseau, so that each cigarette contains three-quarters of a grain of the arseniate of soda, and find them very satisfactory. The patient should inspire deeply three or four times from the cigarette, then wait awhile, and see how he feels. I may say that I have never known any unpleasant effect to be caused by the careful administration, in any form, of arsenical remedies.

The headache and distressing after feelings that so often follow the use of fuming inhalations of stramonium, belladonna, or opium cigarettes and powders, usually make persons averse to their employment, unless the asthma comes on with great force. Tobacco smoking, however, is a general and approved source of relief.

Internal Remedies.—Space permits me to mention but a few of these, and among them I would give the first place to the preparations of arsenious acid. The acid may be given in a granule or pill, in commencing dose of one-fiftieth of a grain three times daily, one hour after food. Over both the catarrh and the bronchial spasm its effect will be found marked and decided, while gastric irritation and tendency to sickness often are much relieved, making one think the remedy may have some special action over the pneumogastric nerve.

The solution of arseniate of soda, in dose of two to five drops in water, may agree better than the arsenious acid in some cases; but if neither succeeds, then it is well worth while to try the following combination: Fowler's solution, two minims; potass. iodid., two grains; liquor ammoniæ, five minims; water, one ounce; three times a day. It will succeed where arsenic and iodide of potassium separately fail to benefit. Troublesome œdema about the face and eyes, remaining after the more severe symptoms of asthma are gone, I have found to give way speedily to tincture of cantharides, in doses of five minims with twenty of spirit of nitrous ether, in water, three times daily. A remedy, strongly recommended by Dr. Gream in 1850, is tincture of nux vomica; and there is no question as to its value in old standing asthma with flatulent dyspepsia and irregular, weak action of the heart. In these cases it goes well, in doses of five to ten minims, with dilute phosphoric acid and tincture of ginger. When Gream employed it in summer catarrh he also used acetate of lead ointment, applied high up the nostrils, a remedy which, like snuff of bismuth subnitrate, would undoubtedly do much to relieve local irritation and congestion.

Another remedy, somewhat similar in action to nux vomica, inasmuch as it agrees remarkably well in cases of asthma with feeble cardiac power, is the citrate of caffeine. Two or three grains of the citrate dissolved in water or in warm coffee are by no means an unpleasant dose, and in such cases as those just indicated, it is unquestionably of considerable value. Where the citrate of caffeine fails to give decided relief to the asthma, it nevertheless, as patients have informed me, greatly mitigates the exhaustion and depression that had been previously experienced after the severity of the attack had passed away.

Sayre's Bandage in the Treatment of Fractures of the Vertebræ.

At the last meeting of the Association of German Surgeons (London *Medical Record*), Dr. Küster (Berlin) said the efficacy of Sayre's plaster-of-Paris bandage in cyphosis had suggested its use in fractures of the vertebræ. He had used the plaster jacket in four such cases. In two cases of fracture of a lumbar vertebra, with symptoms of paralysis of the bladder, rectum, and lower limbs, it had been applied with good result; while no improvement followed in a case of fracture of the third dorsal vertebra. In a case of fracture of the middle part of the dorsal spine, with the formation of an angular projection, and complete paralysis of both arms and legs, and also of the bladder and rectum, Dr. Küster had broken up the callus under narcosis, and applied extension (up to twenty pounds); the result being a complete disappearance of the paralysis. Dr. von Langenbeck had applied the plaster-of-Paris bandage in a recent fracture of the dorsal spine in 1862; it was, however, not well borne, and up to the present day he had obtained better results by placing the patient on a water-bed and applying extension by weights. Dr. Bardeleben (Berlin) was not an opponent in general of Dr. Küster's plan of treatment; but he would recommend that the plaster bandage should not be applied immediately in cases of fracture of the spine, as such fractures were always complicated with other injuries; and it might happen that symptoms of paralysis, which were even strongly marked on the first day, might disappear in a short time without any treatment. Dr. Sonnenburg (Berlin) had attempted, in the Berlin Clinic, to apply the plaster-of-Paris jacket, without narcosis, in the case of a child suffering from disease of the cervico-dorsal region of the spine. During suspension, difficulty of breathing suddenly set in; and the child died in an hour and a half, in spite of tracheotomy and artificial respiration. At the necropsy, along with disease of the lower cervical and first dorsal vertebræ, there was found to be a large abscess extending into the posterior mediastinum; it had not burst. Probably this abscess had caused death by pressing, during the suspension, on the trachea, and on the pneumogastric and phrenic nerves. The spinal cord showed no change. Dr. Basch (Bonn) had become very cautious in the use of suspension in spondylitis. Forcible extension led to the formation of abscesses. He had had under his care a case of fracture of the

spine with disturbance of motion and sensation, in which recovery took place under suspension and the plaster-of-Paris bandage. Dr. König (Göttingen) said that the plaster bandage would probably only come into use in slight cases of fractured spine. In severe cases it would be dangerous to suspend to any important extent. Dr. von Langenbeck treated Pott's disease with the plaster jacket only in cases where the children could be examined daily, and the danger of bed sores be thus averted. Chloroform was to be recommended in the application of the bandage, as it prevented violent movements on the part of the children, and thus obviated accidents. The plaster jacket was not suitable for the treatment of scoliosis. For this he used only Taylor's bandage. Dr. Wagner (Königshütte) advised caution in the application of the gypsum jacket in recent cases of fractured spine, lest the blood extravasated into the spinal canal should undergo compression. In one case he had seen paralysis appear on the application of the bandage, which was, therefore, immediately removed. In four subsequent cases he had allowed fourteen days to elapse before applying the plaster bandage, and recovery had taken place in another four weeks. Dr. Busch (Bonn) recommended the plaster jacket in the treatment of scoliosis. Bed sores could be prevented by a pad of cotton wadding on each side of the projection.

The Electrical Treatment of Dysmenorrhœa.

Dr. J. D. Mann writes, in the *Lancet*, July 23d:—

The now old-fashioned term "neuralgic dysmenorrhœa" still expresses all that is known of the causation of many cases of this disorder. All that can be diagnosed in an otherwise healthy uterus is an irritable condition of the mucous membrane of the cavity, which, under certain circumstances, evokes painful, clonic contractions of the organ. In such cases, when the sound reaches the uterine cavity, the patient experiences pain identical with that of dysmenorrhœa, the contact of the instrument with the neurotic membrane being sufficient to set up irregular uterine action. In this form of the disease much relief is afforded by electricity, the result probably of altered nutrition, and of the direct action of the current on the terminal nerves. Associated more or less with dysmenorrhœa is ovarian irritation or neuralgia. When not dependent upon uterine disease this disorder may be successfully treated by electricity, on the principles already laid down. It is often sufficient to administer a current of eighty-five or ninety dix-millivebers, by means of external electrodes, the anode being placed over the affected ovary or ovaries, and the cathode over the lumbar spine. If the accompanying dysmenorrhœa is urgent, it is preferable to introduce the anode into the uterus, and apply the cathode over the ovarian region. If there is suspicion of ovaritis, electricity is not admissible; but tenderness, with slight enlargement of the organ (recognizable on bi-manual examination), with absence of systemic disturbance, is probably due to passive hyperæmia, and is often greatly relieved by the constant current. The relief afforded in simple ovarian irritation is frequently very striking, a soothing effect being experienced by the patient almost as soon as the circuit is closed. In many cases the result of the treatment will be rendered more permanent by the administration of the following nervine tonic: Valerianate of zinc, valerianate of quinine, valerianate of iron, of each one grain, made into pill; one to be taken twice a day. The pills should be protected by an impervious coating, as the combinations of valerianic acid have an exceedingly disagreeable odor.

Some forms of sub-involution of the uterus are amenable to the action of electricity. Retarded involution cannot be regarded as a disease *per se*, but rather as the result of one or more morbid conditions. Retention of fragments of placenta or membranes, inflammation of the cervix from laceration or bruising during labor, and partial prolapse, are among the most common causes. It is obvious that sub-involution thus produced can only be cured by the removal of the exciting cause, and this is to be accomplished by means other than electricity. Simple sub-involution dependent upon muscular atony, or upon malnutrition, alone comes within the range of electro-therapeutics. For the treatment to be successful it is essential that the disease should be attacked in the early stage. It is well known that prolonged hyperæmia produces hyperplasia of the areolar tissue in the organ or part affected. When once this stage of sclerosis is reached in the uterus, and an excess of fibrous tissue obtains over the muscular elements, absorption becomes a matter of grave difficulty, if not an impossibility. In dealing with a hypertrophied uterus composed of a mass of muscular fibres infiltrated with fluid, and but sparingly so with cellular growth, any method of treatment which will stimulate the nutrition of the organ and accelerate the absorption of the morbid products tends to promote a cure. Such a stimulant is electricity. Unless contra-indicated an insulated sound forming the cathode is introduced into the uterus, the anode is placed over the lumbar spine, and a current of about ninety dix-millivebers is passed for ten or twelve minutes, every alternate or third day. During the first half of each application the current should be stabile; during the latter half it may be interrupted at intervals, in order to stimulate the contractile properties of the womb. While the interruptions are being made it is desirable to reduce the current strength, as the opening and the closing of the circuit are attended by slight shocks, which are very disagreeable, if too strong. The patient should maintain the horizontal posture for some hours after each application. If the uterine wall is so soft as to render the passage of a sound dangerous, a cervical electrode may be used in place of the sound. In a case of sub-involution which I recently treated with electricity, each application was followed by a temporary discharge, and slight pain, of the after-pain type; the uterus was reduced to its normal condition in seven weeks. I need hardly observe that perimetric inflammation, or any latent pelvic disease, is contra-indicant of the internal use of electricity.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——"Aids to Rational Therapeutics," by J. Milner Fothergill, M.D., M.R.C.P. of London, published by G. P. Putnam's Sons, New York, is a paper-covered book of one hundred and twenty-five pages, well worth the small price asked for it, twenty-five cents. It teaches the student and practitioner how rationally to prescribe, a point too much neglected in medical education.

——From the Government printing office at Washington, we have received the "Annual Report of the Supervising Surgeon-General of the Marine Hospital Service of the United States," for the year 1881. This pamphlet, of more than two hundred and forty pages, besides containing very much valuable and interesting information, has an article by E. Hebersmith, M.D., Surgeon U. S. Marine Hospital Service, on Beri-beri, which is well worthy of perusal. It seems from this report, that Beri-beri is a disease produced by some specific atmospheric poison (nature unknown), whose development is fostered and hastened by bad hygienic surroundings.

BOOK NOTICES.

A Pocket-Book of Physical Diagnosis, for the Student and Physician. By Dr. Edward T. Bruen, Demonstrator of Clinical Medicine and Lecturer on Pathology of the Urine in the University of Pennsylvania; Lecturer on Pathology in the Woman's Medical College of Philadelphia, etc., etc. With wood engravings. Philadelphia: Presley Blakiston, 1012 Walnut street. 1881. Cloth, small 8vo, pp. 256. Price $2.00.

The author of the work before us has for several years been engaged in teaching diagnosis to private classes, and it is the substance of the instruction thus given that he has here arranged in book form. The methods of diagnosis are minutely described, and the alterations in the percussion note, in the respiratory murmur and the heart sound, consequent upon structural changes or functional disturbances, are lucidly explained. The whole subject has been treated with thoroughness and care, and the work is one which we can conscientiously recommend to students and practitioners as a reliable guide to the acquisition of skill in physical diagnosis, which justly is regarded as one of the most brilliant accomplishments in the domain of medicine.

Manual of Organic Materia Medica. By John M. Maisch, PHAR. D., Professor of Materia Medica and Botany in the Philadelphia College of Pharmacy.

This publication is evidently designed more particulary for the use of students of pharmacy and druggists, than physicians. The classification adopted is based upon the similarity in the physical and structural properties of drugs, and to those who are not so much interested in their action upon the animal economy, this is a well chosen arrangement. By this selection drugs from the same part of the plant are brought together, and in consequence there are chapters (in Part Second) devoted to roots, rhizomes, flowers, fruits, etc. Part First treats of animal drugs. Part Third of drugs without cellular structure, embracing sugars, gum resins, volatile and fixed oils, etc.

The numerous illustrations, many of which we recognize as identical with those of the National Dispensatory, make the book appear simple, easy, and even attractive, but upon close examination one is disappointed. The book is less interesting than the Organic Materia Medica, published about two years ago; that we thought dry and heavy.

The bare citation of facts, devoid of interesting detail, becomes monotonous and tiresome, and information is less readily inculcated. This being the primary object of such works for students, we consider it, in this respect, quite deficient. The illustrations of microscopic structure are quite an addition to this text-book, but some important sections are not shown, as might be expected, *e. g.*, Podophyllum.

The cuts showing transverse sections of the various roots of sarsaparilla do not show them as they appear under the microscope. They, like many of the cuts, seem to be diagrams—good as far as they go, but are imperfect representations of microscopic transverse sections. Gelsemium is one among a number not sufficiently magnified to illustrate the true cellular structure. Taken as a whole, they are representations which will be of good service to the student of histology in pharmacy.

The metric system introduced in the book is a feature worthy of mention. One thing the book is prominently deficient in is, the omission of the names of the officinal preparations into which the various products of materia medica enter. This point is one in which the student and apothecary should be as well drilled as in the origin, structure, or medicinal properties, and in a work of this kind such an addition would be quite valuable.

Transactions of the New Hampshire Medical Society, at its Ninety-first Annual Session, held at Concord, N. H., June, 1881. pp. 168.

The subject chosen by the president, Dr. G. P. Conn, for his address, was State Medicine. He spoke of the progress already made in State or preventive medicine; how the people are becoming every year more and more interested in matters pertaining to the prevention of disease; how twenty-one States have already established boards of health, and also of the influence of the National Board of Health, and closed his address by an eloquent appeal to every intelligent, public spirited man to join in advancing the interests of public health, by the enactment of laws for the advancement of preventive medicine. Dr. A. H. Crosby read the report on surgery. For this report a paper was furnished by Dr. F. A. Stilling, giving cases of malignant disease, with a report on the use of the Dermal Curette; and Dr. John R. Ham furnished a contribution to the Study of Fractures and Dislocations. Dr. J. W. Parsons read a paper on Puerperal Convulsions; Dr. J. R. Kimball, on Conservatism in the Practice of Medicine; and Dr. D. W. Jones, on Nihilism in Medicine. Several other papers and reports were also read.

Lectures on the Pathological Anatomy of the Nervous System, Diseases of the Spinal Cord. By J. M. Charcot, Professor to the Faculty of Medicine of Paris, Physician to La Salpetrière, etc., etc. Translated from the reports by Dr. E. Brissaud, in the *Progrès Médicale*, by Cornelius G. Comegys, M.D., Lecturer on Clinical Medicine in the Cincinnati Hospital, etc., etc. With illustrations. Cincinnati: Peter G. Thomson, 1881. Cloth, 8vo, pp. 165. Price $1.75.

These lectures, seventeen in number, formed Prof. Charcot's course for 1879–'80, and were reported in the *Progrès Médicale*, by Dr. E. Brissaud. Dr. Comegys' translations first appeared in the Cincinnati *Lancet and Clinic*, beginning in September, 1880, and have now, by request, been republished in book form. As a contribution to scientific medicine they are undoubtedly among the most valuable of recent productions. While they, therefore, will be read with interest by the speculative and philosophical theorist, and while the facts here taught will ultimately lead to valuable practical results, the busy physician will find little to attract him or to turn to practical use. The translation has been well performed, and the book is gotten up in good style.

A Handbook of Uterine Therapeutics and of Diseases of Women. By Edward John Tilt, M.D., Past President of the Obstetrical Society of London; Knight of the Crown of Italy, etc., etc. Fourth Edition. New York: William Wood & Company, 27 Great Jones Street. 1881. Cloth, 8vo, pp. 328.

This constitutes the volume for November, of Wood's Library of Standard Medical Authors. After a brief introduction, in which the study and practice of gynecology are discussed in a general way, the author proceeds to describe the modes of examination and surgical instruments. After which comes a chapter on uterine surgery. Dietetics and home treatment also receive full attention, the remainder of the work being devoted to uterine medication proper and the medicinal agents used in gynecological practice, the treatment of displacements, complications and sterility, with a final chapter on the prevention of diseases of women. The book is one that will be found useful.

Nervous Diseases: Their Description and Treatment. A Manual for Students and Practitioners of Medicine. By Allan McLane Hamilton, M.D., Fellow of the New York Academy of Medicine, etc., etc. Second Edition, revised and enlarged; with seventy-two illustrations. Philadelphia: Henry C. Lea's Son & Co. 1881. Cloth, 8vo, pp. 598.

In bringing out a second edition of his work on Nervous Diseases, the author has availed himself of the opportunity to thoroughly revise the text of the former, and to make such additions as recent advances in neurological medicine would call for, thus enlarging the volume by nearly one hundred pages. Many new illustrations have also been added. This work is well adapted to the wants of the general practitioner, for whom it seems to have been especially written. It is a thoroughly practical book, the careful study of which will render the diagnosis of nervous affections the more easy, and their treatment more successful. Several important cases are recorded, giving the additional value of clinical tests to the teachings set forth. Morbid anatomy and pathology receive full attention, and the results of numerous post-mortem examinations are given.

Being carefully and thoroughly indexed, in plain, large type, containing also a table of contents, as well as a list of illustrations, this book is rendered very useful as a reference work for the busy practitioner, to whom we can commend it.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

WHY NOT CONSULT WITH HOMŒOPATHS?

We do not like to recur often to the relations of homœopathic practitioners to the regular profession. So far as homœopathy itself is concerned, it is now no longer Hahnemannism. Not a single precept of its founder is now respected in full by his followers. Its value as a dogmatic school is, by its own confessions, long since past.

Does that bring it nearer the position it should assume? Is that a reason why its advocates should be recognized by the regular profession?

We say, emphatically, *No.* Homœopathy is now not even true to itself. It is sailing under false colors. It is pretending to the public to be what it is not. It is deluding those who trust to it.

There is no reason why many modern homœopaths should not unite with the scientific part of the profession. Yes, there is one reason, and only one, and this is no credit to them. It is that by unfolding the homœopathic banner they may capture more patients. This, and only this, is the reason that restrains these practitioners from joining us.

It is an all-sufficient reason for the profession to refuse to consult with them. No matter whether therapeutics are alike or not; no matter whether the consultation is intended to be for diagnosis alone; yet it is deteriorating to a man to countenance deception in another; it is compounding a social felony.

Hence we have no hesitation in condemning the recent action of the British Medical Association, which declined to expel a member who had openly turned homœopath. It was said, in defence of their inaction, that to expel him would have advertised him, and enlisted for him the sympathy of the public. Such reasoning is futile. The thing which is right should be done, and let the consequences take care of themselves.

No more do we approve the recommendation of that Association's lecturers, which we recently quoted, to consult with homœopaths, when asked. Such a recommendation is inconsistent with our duty toward our patients, and contrary to the dictates of scientific reasoning. We have shown this repeatedly, and it is not for any such purpose, it is not for the benefit of the patient, that this relaxation of ethics is suggested.

We know the secret motive at its base, and without mincing matters, we shall expose it.

The prominent physicians and surgeons in great cities find their most profitable business in consultation practice, and as a great many wealthy families have homœopathic attendants, consultations in such cases are impossible, if the code is strictly observed. This cuts down incomes very decidedly, and how to get around the difficulty is a frequent matter of thought.

Some are bold enough to go when they are asked, without knowing or caring of what school, color or sex the attending physician is, and spurning the terrors of "the Code" with contempt. Most, however, shuffle and palter, to frame excuses and pay a seeming deference to ethics. A few refuse squarely to meet any but graduates of regular schools.

These are facts, and knowing them, we are not

surprised at the effort of a few London physicians to break down the barriers; nor are we astonished to find that effort seconded in New York city. In one of the late issues of the *Medical Record* is an editorial, clearly aimed at supporting this step, and at introducing it into that city. The motive is unquestionably the same, and it should be exposed. It is not humanity, the welfare of the patient, nor at all the dignity and morals of the profession, which are considered by the advocates of this action, but the pockets of physicians who have a large consulting practice.

Such being the case, no good can be expected from the movement. We consider it one in a false direction, prompted by selfish and unworthy motives, hypocritical, in that it pretends to a higher origin, and unfair to the mass of the profession. Let us retain our principles free from the stain of such imputations. Let us insist that those practitioners who no longer practice homœopathy shall also be honest enough to drop the name of it before we receive them in fellowship.

BIDDING FOR PRACTICE.

A correspondent from a western State asks us, "Is it in good taste, and no infringement of the code of medical ethics, for a medical society in whole, or its members individually, or any medical man, to bid, by sealed proposals or otherwise, for the pauper practice of a county or township?"

This question involves a good many side issues. It is generally held by the most respectable members of the profession, that a physician sacrifices some of the dignity and respectability of his profession as soon as he commences, in any way, to solicit practice. It is the rule, in our profession, that practice must seek the man and not the man the practice. While this custom may seem to some to constitute a hardship, yet in reality it is a most excellent condition, for by and through it is brought into play that most beautiful law of the survival of the fittest. When practice comes to a capable man, as it always will sooner or later, he properly performs the duty which has fallen to him, and from this proper performance of duty receives his advertisement. While the incapable and deficient medical man, though he may for a time *seem* to prosper, eventually fizzles out, as it were, and finds his level.

An exception to this rule, however, would seem to hold in the cases of the specialists of our large cities, who derive their extensive practice and large incomes principally from a judicious course of personal advertising. Note the successful oculist, or aurist, who, in dress suit and white kids, visits the opera. During the intermission between acts, he stands up in the most prominent part of the house, and through an immense pair of opera glasses, eyes the whole audience for some fifteen or twenty minutes. Naturally enough, every one who knows him not at once asks some neighbor who he is; they look and stare at him, and wonder who he is, just as they would look and stare and wonder who any other conspicuous figure might be. Some well-informed member of society announces that it is Dr. So-and-So, the famous oculist, or aurist. The next morning, or within a few days, this person has an eye-ache, or an earache; off he rushes to Dr. So-and-So, who receives him in gorgeously furnished offices, talks to him for ten minutes, prescribes some simple eye wash (well known, in the majority of instances, and frequently used by every well-informed practitioner), charges him ten dollars and tells him to call again. Six or seven such consultations constitute his day's work. Then a handsome carriage and spirited horses, with coachman in livery, appear at the front door, and our specialist goes out for an airing, and to still further advertise himself by his fashionable turnout. Home to an epicurean dinner, after which the opera again, the theatre, or a dinner party.

Such is the routine of our present fashionable *specialist*, and by such advertising he makes plenty of money. In the abstract this is wrong, but since it is sanctioned by society, and encouraged by the liberal fees of the fashionable and

wealthy, it will do no good to condemn it. Since these specialists are usually powers in society, and (to their credit be it said) liberal to the cause of medical progress, therefore, their course is tacitly recognized by the medical profession, since it is not openly condemned. But to answer our correspondent, we would say that the code of ethics would not sanction or approve the act of a physician who would endeavor to procure practice in the manner he mentions, and would hint to him to suggest to the county commissioners the fact that, in all probability, the lowest bidder would be the poorest physician, since in medicine, differently from in trade, the man who possesses the greatest stock of knowledge and experience usually wants the highest price for it.

Notes and Comments.

Premature Menstruation.

Dr. Prochownick, of Hamburg, stated that a district physician had called his attention to a child three years of age, highly scrofulous, who, since one year old, was subject to regular catamenial discharges, lasting from two to three days, every four weeks.

This child died of miliary tuberculosis two days after such a flow, and an autopsy was made twenty hours later. The uterus was not large, but its mucous membrane had every appearance of being *post menses*. Its size, thickness, dimensions, and the proportions between the neck and body, far exceeded those usual in the uterus of a child of that age.

It is interesting, therefore, to observe that this menstruation was incidental to a regular evolution of the ovules.

This case is important, because it shows the primitive relation which must exist between menstruation and ovulation.

Engine Drivers' Deafness.

In the London *Lancet* of December 24th, 1881, Moos makes some interesting remarks on this subject. According to his observations, the drivers and stokers of railway engines suffer, sooner or later, from diminished acuteness of hearing, due to their occupation. Usually bi-lateral, this defect becomes manifest sooner in the men employed on railways in which there are many tunnels, than in those who drive engines in level country. Swaback and Pollnow have arrived at the conclusion that this class of employees almost invariably suffer, in the course of time, from diminished acuteness of hearing; of 160 examined, 20 per cent. were found to be more or less deaf. In most cases a distinctly morbid condition of the membrana tympani was observed, which indicated a sclerotic form of chronic catarrh of the middle ear. It was considered by these observers, that this diminished acuteness of the sense of hearing was not dangerous. We must agree with the editor of the *Lancet*, that the engineer of a locomotive has so much responsibility resting on his organs of special sense, that it is imperative that all of his senses should be perfect, and their acuteness entirely unimpaired. This is a question open to practical demonstration, and it would be well for railway officials to turn their attention in this direction.

Circumcision as a Sanitary Precaution.

Dr. Edward T. Williams, in a paper read before the Norfolk District Medical Society, November 29th, 1881, and published in the Boston *Medical and Surgical Journal*, thus discourses on the sanitary value of circumcision: "It probably does good in several ways.

"1st. The exposure of the glans penis to the air and to friction from the clothes dries and hardens its surface, and renders it less liable to abrasion in sexual intercourse, and consequently to venereal ulcers.

"2d. The removal of the foreskin is acknowledged to be useful as a preventive of masturbation. It not only renders the act itself more difficult, but by diminishing the sensibility of the part and favoring the removal of irritating secretions, diminishes also the propensity to the act.

"3d. It prevents the accidents of phymosis and paraphymosis.

"4th. It prevents the retention of the sebaceous secretion and the ensuing balanitis.

"5th. It probably promotes continence by diminishing the pruriency of the sexual appetite."

Fashion vs. Health.

From a secular newspaper, we notice that a woman of good form is only spoiled by the corset. The curves of the body are all outward curves, one arising out of the other. But the chief curves of the corset are inward curves, which are not only incorrect, but are the source of great damage, in compressing unnaturally the organs of the body. Another objection to the corset is in the bones, whose rigidity obscures that rippling movement

of the body which is one of its chief beauties. As far as this is concerned, the body might as well be incased in cast iron. Another objection is in the hard cross line of the bust, which distinctly shows, as do often the laces, under a tight-fitting dress.

With pleasure we read every effort on the part of the secular press to urge the public to place health before fashion, and trust that this very important suggestion will be made public everywhere, and that physicians will use their very best efforts to induce their patients to be guided by it.

Poisoning by Aconite.

The coroner's hearing in the case of Dr. Lamson, the son of the American clergyman at Florence, who is accused of having poisoned his brother in-law at Wimbledon, with aconite, is still in progress. Some very elaborate experiments are being conducted by Drs. Stephenson and Dupré. A case of poisoning similar to this had not taken place for a long period, the time being given by some persons at over 100 years. It is natural, therefore, that the symptoms presented should be new, and in order to form an accurate judgment of them, it is intended to experiment with aconite upon the bodies of animals.

A later despatch from London, says the coroner's jury in the case of the young student, Percy M. John, who died at the Blenheim House School from the effects of poison, as ascertained by medical investigation, has found a verdict of willful murder against Dr. George H. Lamson, brother-in-law of the deceased. Dr. Lamson is the son of the American chaplain at Florence, Italy. It was brought out in the course of the present case, that the deceased student was entitled to the sum of £3500, which, on his death, reverted to his sister, the wife of the prisoner. Just previous to Percy's death, the prisoner was in want of money and had pledged his watch and surgical instruments. He pretended to go and see the young student, and said that the youth was very sick and could not live long. He administered some medicine to him which, it was ascertained, was aconite in the form of a capsule. This caused Percy's death. The day the young man died, Dr. Lamson left for Paris.

Health of New York.

In glancing over the vital statistics of New York, for 1881, several interesting points are noted. We all remember how filthy the streets of that city were last winter and early spring, and now we see that the death rate last year was 31.07 per 1000, while in 1880 it was only 26.47 per 1000, and only 24.50 per 1000 in 1877. Smallpox carried off 450 persons, as against only 81 in 1880 and 2 in 1878. Diphtheria was fatal to 2237 persons. Children were born in five instances to mothers who were under fifteen years of age, and in three cases to women over fifty. One mother was but 13 years and 10 months. 472 of the fathers were over fifty, while 58 were under twenty years. 17 persons over one hundred years old died, one of them, an Irish woman being 110, one 106, and three 104. Eleven of these centenarians were women, and six men.

True Cause of Malaria.

The *Public Ledger* says: It has been remarked that in very many cases in the upper part of New York City where cellars are being excavated and much old soil is being upturned, the inhabitants of the neighborhood suffer from malaria. We can readily believe this to be true, since the element necessary for the production of malaria (organic material) is, by cellar excavation, brought into a condition in which it is capable of producing malarial poison. In other words, organic matter is exposed to heat and moisture, and decomposition results. This practical demonstration in New York, is an additional argument in favor of the theory that organic decomposition is, in all cases, the cause of malaria, which really means nothing more than bad air, rendered bad by the admixture with it of the results of organic decomposition.

Cigarettes.

"'Cigar smoke puffed in a man's face by another man is assault and battery,' says a New York Judge. If that is the case, cigarette smoke puffed anywhere in one's neighborhood should be considered murder in the first degree."

This is a true condemnation of cigarette smoking. It is a fact, not disputed, that the majority of cigarettes are not only made of the most inferior tobacco, cigar stumps from syphilitic mouths and filthy gutters, but that both paper and tobacco do contain much poisonous drug adulteration.

Quadruple Amputation.

In the New York *Medical Journal*, Dr. W. S. Tremaine, Assistant Surgeon United States Army, reports the case of a soldier who was brought into the hospital at Fort Dodge, with both hands and feet completely frozen. Amputation of both hands and feet was performed, and the patient recovered.

Sudden Death During Forced Depression of the Tongue.

A woman sixty years old, suffering from tinnitus aurium and partial deafness, applied to Dr. Moure, who ascertained the existence of catarrh and obstruction of both Eustachian tubes. Wishing to examine the pharynx, he directed the patient to open her mouth; the tongue being in the way, he introduced a depressor. No sooner had he depressed the tongue than the patient drew a hissing inspiration, and commenced suffocating. Believing he had to deal with a spasm of the glottis, the Doctor had recourse to artificial respiration, but asphyxia increased, râles set in. Tracheotomy was then practiced, but asphyxia continued, spumous blood was discharged through the cannula and by the mouth, and the patient expired.

The Doctor believed that the spasm of the glottis occasioned by a forced depression of the tongue would not of itself have been sufficient to cause death in a strong and healthy person, but in the present instance, the patient being under some emotion, an old cardiac affection had probably been awakened, and a rapidly fatal congestion, or apoplexy of the lungs had followed. This opinion was to some extent borne out by the fact that the patient showed marks of scarified cups under the left breast.

In commenting on the above case, the editor of *Paris Médical* (*No.* 46) observes that it accords with what he has long ago published on asphyxia caused by enforced immobility of the tongue. If a patient's mouth be immoderately opened by means of a gag, the tongue can no longer move, deglutition of saliva becomes impossible, and the larynx is immobilized. Under these conditions rapidly fatal asphyxia can be produced. An instance of it has been observed. Satisfactory evidence may be obtained from the following experiment: Let the tongue be immobilized by placing a finger upon it, the mouth being opened or closed; or let the jaws be kept wide open by a bit of wood inserted between the teeth, and the result will be a respiratory anguish which, if prolonged, would lead to asphyxia.

Imagination a Cause of Death.

The following item will be of interest, since it seems to prove that imagination may obtain such control over a man as even to cause his death: "The coroner's jury who investigated the death of Frederick Miller, at the Second District police station, from the supposed effects of hydrophobia, adopted the view of Dr. Duvall, who attended Miller, that his death was due to exhaustion, the result of acute mania; in other words, that he frightened himself to death." We believe that imagination and fear really did cause death in this case. The man was bitten some time since by a small dog, and from that time up to his death he was constantly apprehensive that he would have hydrophobia. Finally, when he did die, the symptoms presented would not at all carry out the supposition of hydrophobia, and the verdict of the coroner's jury was perfectly justified by the facts.

Stretching of the Lower Dental Nerve—Cure.

At a meeting of the *Société de Chirurgie*, Nov. 18th, Mr. Polaillon mentioned the case of a man, 61 years old, who for several years had suffered from neuralgia of the fifth pair, medical treatment having failed in affording relief. Mr. Polaillon performed an elongation of the lower maxillary nerve on the 6th of September. The patient having been anæsthetized, the tissues incised down to the inferior maxillary branch, on a level with the lower dental canal, a small crown of 13 millimeters diameter was used with the trephine, and the nerve having been laid bare it was taken up on a hook, and stretched about 15 millimetres. A Lister dressing was then applied. Three days later there was a slight return of pain, which was controlled by anæsthetics. Since then there has been no relapse.

Special Reports.

No. II.—ON THE EXAMINATION OF DEAD BODIES IN SUPPOSED CRIMINAL CASES.

BY GEO. F. SOUWERS, M.D.

It not unfrequently falls to the lot of the practitioner to be called upon to testify or render an opinion in court, or before a coroner and his jury, in cases where there is more or less of an air of suspicion surrounding the circumstances under which a person has met his death. The physician, in some instances, fortunately, sees the deceased upon whose death inquiry is being made while the individual is yet capable of accounting for the events which resulted in the production of his wounds and bruises, and while he can yet tell his name, age, etc., etc.; but, unfortunately, it at times happens that the doctor does not reach the case until death has stepped in and left to conjecture the cause of the taking off. As coroner's physician, or as an expert, he is called upon to examine the corpse and to render an opinion as to the age, cause and time of death of the body found. Before considering the method of examining a dead body and the

observations to be made and inferences drawn, we will consider the case suggested in the first proposition spoken of above, namely, a man seen who is either in or rapidly approaching articulo mortis. In such a case the doctor should be very careful to weigh carefully every word uttered, not only by the sick man himself, but by every one, even to the youngest child, present; for it may happen that the old adage that "fools and children tell the truth," may receive an exemplification. He should be guardedly jealous of every word of opinion he utters, taking care to express no suspicions to any one, but noting all suspicions expressed by others, for one of two things may transpire from a neglect of these precautions. In the first place, if he unthinkingly utters his suspicions, it may transpire that the suspects may take alarm and escape before the law has an opportunity to lay its hand upon them; or if he is careless about noticing the suspicions of others, it may happen at times that very valuable clues may be lost; and in this connection it is essential that everything transpiring be committed, either *at once* or *as soon after as possible*, to writing, which writing should not be permitted to go out of his possession for a moment, as otherwise it might be tampered with or altogether destroyed, by those who might be compromised.

All statements made by a person grievously wounded or *injured*, where either suicide or the commission of a crime is suspected, as well as in all cases of accidents, as from a person being run over by a railway car, etc., etc., should be, where possible, *immediately* reduced to writing, then read to, and finally signed by the patient, in the presence of witnesses. We suggest that this precaution be taken where injuries are the result of accident, from the fact that not infrequently suit is instituted by the survivors, against corporations and individuals, for having, by their negligence, caused the untoward event to the deceased by which he met his death, whereas the declarations of the person himself may prove beyond peradventure that he was a contributor to his own death, by personal carelessness or risks run; while personal sympathy for the unfortunate surviving relatives, might tend to induce the physician to allow such claims to be made, on the common principle that corporations, etc., should be made to pay for accidents occurring to individuals in the transaction of business, yet he must remember that he stands in the light of a disinterested party; that he, as far as in him lies, must see justice done to each and all, and in prosecution of the duties of his position he is bound to use all reasonable means in his power to assist the law; and a court would be justified in expecting thus much of him. When dying declarations are made, the condition of the one making them should be closely noted; his temperature, nervous condition, mental state, etc., should be noted, in order that, if the question should arise during a trial, as to whether, at the time of the making of certain statements, the deceased was in a rational state; or whether either the attendant or the patient considered that death either was inevitable shortly, or that it was already upon the individual, a reliable answer could be rendered. Any expressions by or actions of the patient indicating that he had no hope of recovery, and that *he was satisfied* that he could by no possibility recover, should be observed by the medical attendant, for certain courts have held, at different times, that for the declarations of a person who shortly afterwards died of the injuries he was then suffering under to have the sanctity and binding force of an oath, they must be made with a feeling or knowledge on his part that he could not by any possibility recover. While this rule has been often set aside or rejected by the judges, in late years, yet no one can tell what question may come up in a criminal trial, or a suit for damages as against corporations, etc., and it is as well to have as *direct* and complete evidence as can possibly be obtained; it has been held that a dying declaration is fully as binding as an oath, from the fact that the awful sense of impending dissolution will so overmaster an individual as to compel him to speak the truth, no matter what revenges, etc., he might personally wish to gratify, or what benefits, as in cases of suicide to obtain an insurance money, he hoped to confer on his family, and which could only be obtained by making false statements, as when in the latter case a provision is in a policy providing against payment of the loss if a person die by his own hand, he should make statements that he had been wounded by others, while we might be supposed to accept the statement as that of a man about to go into the unknown, yet we should remember that there are individuals of such strong force of character that a fear of death would not turn them from a course decided upon to be pursued, and hence, the rule of the old courts would not hold; further, few men, no matter how desperately wounded, give up *all hope* of recovery so long as a spark of clear reason is left them; no matter how demoralized and morally panic stricken they may become in contem-

plation of the extent of the injuries sustained, they in some way, in ninety-nine cases out of a hundred, show that there is yet a lingering hope that all will be well with them. The principle may be summed up in the sentence that "*there must be a conviction of approaching death.** Care must be taken not to ask leading questions of a person under the conditions being considered. A leading question, roughly defined, may be said to be one that can be answered by the reply "yes," or "no;" for instance, to say to a man "It was John Smith who wounded you, was it not?" would be a leading question, for it would almost necessarily have to be answered in one of the two ways mentioned; the reason of this precaution is that a name or person being suggested to a dying individual, might readily be adopted and accused by him, without his hardly being aware of what he was doing, or the vital importance of the question he was replying to; in fact, in this way a person might readily be involved, through the spite and contrivance of others who wished to accomplish ends or revenges of their own. *If a medical attendant is satisfied that his patient will not recover, or that the chances are so decidedly against recovery as to amount almost to a certainty of death, in cases of the nature we are considering, it is his bounden duty to so inform the patient,* for if he does not, we question whether the law should not hold him responsible for such negligence as may result in a miscarriage of justice.

Let us go back and take up the second part of our first proposition, where death has already taken place before the physician's arrival, and starting from the time of entrance upon the premises, follow each step that should be taken in making a medical examination in cases of the kind under discussion. Upon entering, a physician should note carefully the condition and appearance of the surrounding ground or pavement, the steps, door knobs, and jams, and such wood work as might be able to furnish evidence of the manner in which and place at which the person had been wounded. For instance, the following story might be told and receive credence by the unsuspecting physician; that the man had committed suicide in the room in which the body is found; whereas, this story might be the veriest fiction, which could be demonstrated if it had been observed by the doctor that the ground in some locality close to the house had recently been trampled, or that blood spots had been seen on the steps, door knobs, etc., in parts of the house more or less remote from or leading to the place in which the body is found (we are supposing, now, that the person has died of open wounds); for if any of these conditions were found, it would be a fair presumption that the man had not died by his own hand, and in the place stated, but that others must have been concerned in the death of the individual, the blood stains being left by those who were concerned in the person's taking off, and who had carried the body to the place in which it was found by the doctor. The character of these stains and spots should be carefully noted, whether they have a daubed and streaked appearance, or whether they are such as would be caused by blood thrown from the open mouth of an artery; the question of the character of these stains might well be raised in a trial for murder, where the defence was that of suicide; thus a spattered condition of the walls and wood-work of a stair landing only, would of necessity show that an arterial wound had been inflicted before the entrance of the person into the room in which his body is found, and this circumstance might make a very material difference in the acquittal or conviction of a prisoner. Further care should be taken to notice whether the spots or stains have the appearance of freshness, or age, whether they are thoroughly dry, or whether they are still either decidedly wet, or so moist as to be readily rubbed off by a dry body, like the finger or a fine linen rag, for this, again, might be made to bear upon the question of how long a time has elapsed between the exudation of the blood and the finding of the body. If it were still in drops, or readily removable by a slight wipe, it is evident that it could not have been ex corpora for any length of time, or this condition would not prevail. Notice should be taken whether the furniture and hangings of the different apartments are in order, or whether they are disordered and torn; care also being taken to notice whether trunks, secretaries, or other articles likely to contain valuable papers, etc., are open, and having the appearance of having been searched; for a question of this nature might well arise, was there any reason to suspect that the deceased was murdered? either for the purpose of robbery or to secure papers, etc., the possession of which might be of particular interest to the parties suspected of the commission of the crime. In such a case it would be a matter of great interest to know the condition of pieces of furniture, etc., in which such papers would be likely to be kept. Upon approaching the place where the body reposes, care should be taken to narrowly, but

* "Taylor's Medical Jurisprudence," by Hartshorne, page 179.

in no way obtrusively, watch the emotions and behavior of those upon whom suspicion may fall, whether they assist, resist, or in any way attempt to put obstacles in the way of a thorough examination; for all these questions may arise in the course of a criminal trial, and may be used either to the damage or the benefit of accused persons. Before proceeding to examine the body, any instruments, ropes, keys, etc., broken china, or glass ware should be carefully looked for, examined, their condition being noted in writing, and placed in a secure receptacle, which should be retained in the possession of the physician till disposed of, as we shall discuss later.* Where the case has died of poisoning, without a physician having been present previous to death, all vomited matters, bottles, boxes, or papers of powders; whatever excretions, such as urine, etc., that are obtainable; portions of the last meal and drink partaken of by the patient; and any stained pieces of clothing, etc., used by the deceased, should be carefully preserved in air-tight jars (with glass stoppers or covers), sealed and labeled. In regard to food and drink, it is advisable to secure, not only a portion of the common dish from which all are supposed to have been served, but also, when possible, the remnants remaining on the particular plate, or in the cup or glass, of the deceased, for it has not been an unknown thing for a part, and not the whole, of a repast to be criminally prepared, where it is intended to get rid of an individual, and the finding of deleterious matter in one portion and not in another would be evidence of criminal intent on the part of some one.

(*To be Continued.*)

Correspondence.

Some Points in Malarial Fever.

Ed. Med. and Surg. Reporter:—

One of the most unfortunate terms ever introduced into medical literature is *typho-malarial;* unfortunate, because incorrect. Though it has been discarded by Dr. Woodward, the one who introduced it, the usage of the term is rife in malarious regions. Only a few weeks ago, I remarked to an intelligent practitioner that the malarial fevers of this year are of an unusually intense type. "Yes," he replied, "and there is no doubt they have associated with them a 'typhoid element.'" But, I answered, you do not think the specific typhoid and malarial poisons are conjointly at work in the same individual? He said that he did, and referred me to Dr. Woodward's work, as sustaining such a view. That man knew that Dr. Woodward had formerly enunciated such a belief, but he did not know that he had repudiated it absolutely, in a paper read before the International Medical Congress, at Philadelphia. Typho-malarial fever has no existence. Typhoid fever and malarial fever never exist contemporaneously in the same subject. Too often, in malarious regions, it is found *convenient* to apply the term typho-malarial to grave cases of remittent fever; or a simple malarial fever is said to "turn typhoid" when it assumes a dangerous aspect. It is a disgrace to the medical profession to have such opinions scattered among the people, and when one physician expresses such notions to another, it is difficult to tell whether his knavery or ignorance preponderate.

It should be known that few fevers are more malignant than the ordinary remittent, when improperly treated. It should also be known and remembered, that just as we have pernicious intermittents, so we have pernicious remittents, and that for such a fever to assume grave features or to end fatally it is not necessary to have it *become* either typhoid or typho-malarial. To have typhoid fever *modified* by a malarial element is quite another thing, but it does not become a separate disease. In the same sense do we see scarlet fever or whooping cough modified by a malarial element.

I have been thus definite with reference to this matter, because the notions that have been refuted are so exceedingly common in malarious regions. Throughout the malarial regions skirting the Susquehanna, the fevers incident thereto have been, during the season just passed, more than usually grave and stubborn. The only variation from the usual course, however, has been the intensity. In spite of the most effective treatment many cases have lasted from two to three weeks. As a rule, the attack would be preceded by a few days during which the patient would be warned of an approaching illness. He would say he felt tolerably well until a certain hour of the morning, it might be, but as the day wore on he would complain of lassitude, of inability to concentrate his energies. There would be more or less headache, with aching in the back and limbs. In a majority of cases the bowels were either constipated or relaxed. Thus on until the malady was fully developed. Sometimes it would be ushered in by a feeling of chilliness, never violent, in my observation. Again, the patient would deny ever having experienced the least coldness.

Upon examination now, the thermometer would record an axillary temperature of from 102° to 104°. There would be headache and backache of moderate intensity. Usually nausea, sometimes not marked for a day or two, but eventually coming on. Occasionally a case of the utmost gravity would run its entire course

* A case in point has just arisen in this city, involving the question of the finding of fragments of broken china. A woman was found dead in a room in a disreputable portion of the city, with certain wounds of the head, which might or might not be the result of a fall. She lived in this room with a negro, and it was in evidence that both partook, more or less freely, of liquor. The claim was that she had fallen to the floor and died; but on the floor the shattered fragments of a pitcher were found, with which it was charged she had been beaten over the head, inflicting mortal injuries. The case, however, has not yet come to trial, but we can see how one circumstance will bear on another.

without vomiting, but never without nausea. Sometimes the tongue would be coated thickly, but more frequently not.

Another marked symptom, and, according to the writer's observation, invariably present, was the gastric uneasiness. I say uneasiness, but it was frequently complained of as the most painful feature of the entire illness. In a majority of the cases under my care the patient would bleed from the nose once or twice during his illness. This feature was never noticed, except in those cases in which constipation was a marked condition. Except in one case, I never was able to discover the slightest moisture of the skin till near the termination of the disease. In fact, perspiration may be regarded as a harbinger of successful issue, and it also denoted the speedy breaking up of the disease.

As to the remissions spoken of in the text-books, and observed in cases of moderate severity, they were not noticeable after the first day or two of the disease. They were marked and regular, however, as the violence of the fever abated. I have been at much pains to ascertain this point. I should have noted the fact that sleeplessness was a prominent feature during the early days of most cases.

If the case did badly, the observer would notice that while, during the early days of the disorder, the whole system seemed to be laboring at high tension, there was now a very considerable depression of the forces, and if proper treatment were delayed, there would be developed a numbness of the extremities, delirium, picking at the bed clothes, extreme restlessness, twitching of the tendons, involuntary relaxation of the sphincters, etc. Many cases in this vicinity have assumed just such features and have terminated fatally.

Diagnosis.—As we believe the mistake most frequently made in the detection of malarial fever to be a confounding of it with typhoid fever, we shall simply discuss briefly the prominent points of difference. No matter what degree of severity may be assumed by malarial fever, we never have the tympanitic abdomen, nor any eruption, as we do in typhoid fever. We may have diarrhœa, though usually the opposite obtains. I met with one case during the past autumn, in which diarrhœa was a very troublesome feature; the patient would have from two to five or six loose actions daily. Again, the thoracic symptoms, so common in typhoid, are absent.

In the temperature record, too, we have valuable data; it is only necessary to remember the peculiarly uniform record of typhoid. In short, the difference is so great that careful practitioners can never err.

Treatment.—It seems to the writer that, at this day, no case of malarial fever, however grave, should terminate fatally. The mistake most commonly made is to purge the patient. I feel justified, by experience, in laying down the statement that a malarial fever patient should never under any circumstances be actively purged. The best results are obtained by letting the bowels entirely alone, save under a circumstance to be mentioned below. I need scarcely state at this day, that the one remedy to be relied upon is one or other of the salts of cinchona. But, above all, allow me to impress the fact that no conservatism should be practiced here. Whichever of the salts of cinchona you use, use it unsparingly and with a fearless hand. If you use sulphate of quinia, give it in from twenty to thirty grain doses, repeated from three to four times in the twenty-four hours. If it is vomited, at once repeat the dose, or administer it hypodermically, or by the rectum. I have learned by the frequent abscesses consequent upon the hypodermic method, to greatly prefer the rectal injections. If the remedy does not seem to be taking proper effect, a one-grain dose of calomel now and then will greatly favor its absorption from the stomach. Quinia so given has a vastly better effect than even the same quantity in divided doses. This can only be a question with those who have had no experience with the treatment by large doses. Now, let us glance cursorily at the diet, and at the treatment of the prominent symptoms. The patient will crave nothing; nothing tastes natural to him; and, as a rule, the best way is to urge no food while the fever rages in its intensity. After this, and during convalescence, allow him anything he may crave and feed him well, beginning, of course, with an easily digestible aliment.

The nausea in most cases will be intense and it is well to attempt relief, though you may try everything and be utterly foiled. Sometimes small doses of calomel (from $\frac{1}{12}$ to $\frac{1}{6}$ gr.), as recommended by Bartholow, will relieve. Warm water will in some cases produce the desired effect. I mention these two plans because they are most effective as a rule, *i. e.*, where anything will do good. The patient will experience great comfort, and not unfrequently great benefit, from bathing, or rather sponging with tepid water, to which has been added a little bay rum. This may be repeated from two to five or six times per day. He should be allowed a moderate amount of liquid, yet not as much as he sometimes craves; in general, the better plan will be to allow him to suck a moderate quantity of ice. Stimulants should not be given early, but upon the yielding of the malady will be found of advantage, according to the exigencies of each particular case. It is occasionally necessary to control the sweating of beginning convalescence, and in no way can this be better done than by a $\frac{1}{4}$ gr. of the ext. of belladonna once or twice a day. Of course, the sweating should not be interfered with, unless the condition or comfort of the patient demand it. The medicines which the writer is in the habit of using during convalescence are either the ferrated elixir of cinchona or Aitken's syrup of the phosphate of iron, quinia and strychnine.

Delta, Pa. J. W. Hickman, M.D.

News and Miscellany.

Utilization and Purification of Sewage Water.

On account of the numerous complaints from inhabitants on the banks of the Seine, below Paris, a commission was appointed by the Minister of Agriculture to investigate this subject.

The commission determined: 1st. That some immediate action should be taken to prevent the infection produced by the passage of the sewage

of Paris into the Seine. 2d. That the only system which, up to the present, has proven efficacious and stood the test of time, is the mixture of sewage with earth. 3d. That all excrementitial products should be excluded from the sewage, and then it could be mixed with the earth, on the Peninsula of St. Germain, under the following restrictions: The liquid should be allowed to flow over the land at regular intervals, and, as far as possible, each time the same quantity of sewage. Organic insoluble products should not be allowed to accumulate on the surface of the ground, but should be well worked in with the spade.

A system of drainage would be needed to allow the escape of the irrigating liquid, and chemical analysis of the water of the river below should be made, to determine if the epuration is perfect. The quantity of liquid for irrigating each hectare of ground could be determined later, after a series of chemical analyses.

Finally, it was resolved that a permanent commission of five members ought to be appointed to supervise these works, and see that all the conditions were faithfully fulfilled.

Remarkable Apparatus for Garroting Unsuspecting Physicians.

A new system of garroting has been invented in Berlin, by a most dangerous criminal of the name of Wilke, who, fortunately, is safe in the hands of the police. Recently two men, conscience stricken, presented themselves before the authorities, accusing themselves of having conspired with a locksmith (the man Wilke), to hire furnished rooms in different parts of the town, for the purpose of extorting money, in the following manner. One of them was to go to bed, pretending to be ill, and send for a doctor. As soon as the physician arrived and bent over the bed, an iron collar of a special contrivance, hid beneath the counterpane, was to be applied to his neck until he had signed a bill of exchange; then he was to be strangled and thrown into a canal which was close at hand. Wilke had devoted much ingenuity to the construction of this instrument, which they described as something like a pair of tongs or pincers fixed on the end of a long iron tube, with a winch at the bottom, by means of which the tongs could be made to close as tight as one liked. The peculiar virtue of this nefarious invention was to consist in preventing the victim from crying for help by immediately depriving him of the power of utterance. To make matters still surer, Wilke had also constructed two steel traps for the victim's feet. The conspirators had begun hy hiring a room at No. 59 Elizabeth-Ufer, where the Schiffahrts-Kanal has an unusual width, and would facilitate the disposal of dead bodies. That very evening, the penitent accomplices declared, had been agreed upon for committing the first murder, and Dr. Lehrs, living close by, on the Kaiser-Franz Greædier Platz, was selected as the first victim.

As soon as this confession had been made, policemen were sent to the house mentioned, where they were told that a man who pretended to be employed in the Government Office for Weights and Measures had, a few days ago, hired a room and paid a fortnight's rent in advance, but that he had not shown himself since; he had, however, sent a trunk into his room the day before. The directory having been referred to, and showing that no person of the name of Wilke was employed in the office in question, the constables proceeded to open the trunk, in which they found two man-traps and all the component parts of the garroting machine. The trunk was carefully reclosed, and the landlady warned not to say a word about the visit. An agreement was then come to between the police and Wilke's two accomplices, that the latter should at first assist their comrade in carrying out his diabolical plan, and only turn round upon him when the victim's life was in danger. Several constables were concealed in a neighboring room, and at seven Wilke appeared, entered his bed-room with his confederates, went to bed, and sent for Dr. Lehrs. Instead of the latter, a policeman came in disguise, and inquired after Wilke's health. The ruffian at once sprang up and applied his pincers to the pseudo physician's neck. The latter, having managed to make Wilke understand that he had very little money about him, he was requested to fill up a check. On his refusal, Wilke turned the winch, until the victim began to be afraid for his life, and began stamping on the ground. This was the signal for the accomplices to let the constables' hands loose, and for the police to enter and seize the criminal in the very act.

The Coming Sanitary Exhibition in Berlin.

An exhibition of books, models and drawings relating to hygiene and safety appliances will be held in Berlin from June to October next, in which American inventors, scientific and industrial men, institutes, boards, etc., interested in sanitary enginery, are solicited to participate. Inventions and machinery for cleaning streets, providing towns with water, lighting, public baths, plans of tenement houses, factories, heating and ventilating systems, food products, steam, horse and electric railroads and kindred appliances will be largely displayed. In addition to these, plans for life-saving by fire, protection against lightning, inundations, explosions, mine accidents, and art works and pencilings will be included. The exhibition is managed by a chief committee, composed of a number of prominent practical and scientific men and able officers, under the presidency of the Staatsminister, Dr. Hobrecht. They are assisted by special committees in all larger towns of Germany, Austria and Switzerland, consisting of the leaders in the different departments of sanitary engineering. Dr. Bruno Terne, of No. 20 South Delaware avenue, is in possession of the plans and details of the exhibition.

Dead and Missing for 1881.

The death-roll of the Coroner of Philadelphia for 1881, embracing a list of 1915 cases, shows that 108 persons died during the year without leaving a single clue to establish their identity. Of this number 67 were infants abandoned at birth; 38 of the

unknown were men and 3 were women. Twenty-seven bodies were found floating in the river, the greater portion of whom were suicides, and five men were run over by the cars. The records of the Police Department disclose 195 cases reported as missing or having run away, 45 of whom were afterwards found. Fully one-half of this number were boys and girls who, having drunk in the inspiration derived from reading dime novels and other productions of that character, ran away from home to seek fame and fortune.

A Fatal Disease Contracted from a Horse.

A curious suit for damages has been brought against the Hestonville, Mantua and Fairmount Passenger Railway Company, by Widow Mary Loughrey. Michael Loughrey, who was Mrs. Loughrey's husband, was employed as a driver by the company, early in 1880. The horses attached to his car, it is alleged, were afflicted with glanders. Michael contracted the disease. Dr. D. Hayes Agnew and other eminent physicians were called in, but they could not control the malady. Loughrey suffered intensely for about six weeks, when he died. Mrs. Loughrey claims that the company was legally obliged to employ horses of sound health. She claims $20,000 damages for her husband's life, sacrificed, as she charges, through the company's neglect.

Items.

—*Braithwaite's Retrospect* for December, 1881, quotes the MEDICAL AND SURGICAL REPORTER fifty-four times.

—The female wards of the Norristown Insane Hospital are under the charge of a female physician. Since the County Medical Society have decided to admit women to membership, it seems perfectly proper that they should be given an opportunity to demonstrate their capacity for public professional positions of trust. Furthermore, this lady physician is said to have been very successful in her moral treatment of those under her care, and to have acquired wonderful influence over them.

OBITUARY NOTICES.

—Dr. William E. Butler, a staff officer of General Jackson in the war of 1812, died at Jackson, Tenn., a few days ago, aged ninety-two years. Once he was defeated by Davy Crockett for the Tennessee Legislature. He owed his defeat to the fact that he had carpet on his floor. Crockett proclaimed from the stump: "Why, my fellow citizens, my aristocratic and wealthy competitor walks every day on store goods finer than any of your wives or daughters ever wore."

—Dr. Orlando Fairfax was found dead in his bed on the morning of January 11th, 1882, in Richmond, Va., where he had resided since 1861. Born in Alexandria, Va.; he was a graduate of the Universities of Virginia and Pennsylvania. He was member of the younger branch of Lord Fairfax's family, and was 76 years old at the time of his death.

—Dr. George W. Pape, of Baltimore, son of the well known German physician, Dr. G. Edward Pape, committed suicide on January 8th, by taking morphine. The young man had suffered from malaria for two years, in consequence of which he was very much depressed in spirits, and in a fit of utter despondency he committed the deed.

QUERIES AND REPLIES.

ED. MED. AND SURG. REPORTER:—

Dear Sir: Will you be kind enough to send me a formula for a good *embalming* injection, and state about the portion necessary for *one body*. Is chloride of zinc or arsenious acid the best? Please favor me with an answer and greatly oblige. W. N. SHERMAN.

Answer.—Prof. Leidy, of the University of Pennsylvania, informs us that the neutral chloride of zinc, as prepared by Powers and Weightman, is the best injecting material. About two quarts, with half that quantity of water, will usually suffice for a body, but Professor Leidy adds, to inject as much as the vessels will contain. Arsenic makes the body look more natural, but will not preserve it so long. The chloride of zinc, as given, is what they use in the University to preserve and keep bodies through the summer.

MARRIAGES.

HERITAGE—CLARK.—On January 6th, 1882, at the M. E. Parsonage, Mantua, N. J., by Rev. W. Williams Christine, Paul S. Heritage, M.D., of Mantua, and Miss Emma M. Clark, of Wenonah.

KRISE—BEETEM.—On Tuesday evening, October 4th, 1881, in the English Lutheran church of Carlisle, by Rev. C. S. Albert, assisted by Rev. A. H. Kremer, D.D., C. Worth Krise, M.D., and Miss Emma F. Beetem, both of Carlisle.

LEWIS—COOPER.—December 29th, 1881, at the residence of the bride's parents, by the Rev. Robert Edwards, Joseph Cresswell Lewis, M.D., of Frankford, Philadelphia, and Miss Eliza Campion, daughter of William Penn Cooper, Esq.

LOGAN—OLMSTEAD.—In Scranton, Pa., in the First Presbyterian Church, December 29th, 1881, by the Rev. S. C. Logan, Harry V. Logan, M.D., eldest son of the officiating clergyman, and Mary M., only daughter of Richard W. Olmstead, Esq., of Scranton.

RANKIN—McCLELLAND.—November 29th, 1881, by Rev. William M. Taylor, Dr. J. M. Rankin, of Richland, Kalamooza county, Michigan, and Miss Martha A. McClelland, of Mount Jackson, Lawrence county, Pa.

STARR—BROWN.—In New York, on Monday, December 26th, 1881, at the East Baptist Church, by the Rev. H. G. Mason, Dr. Alfred R. Starr and Miss Lizzie L. Brown.

TAYLOR—PAUL.—At the residence of S. J. Paul, December 1st, 1881, by Rev. J. L. Thompson, assisted by Rev. J. M. Jones and Rev. S. M. Good, Dr. A. O. Taylor and Miss Maggie J. Paul, all of Delmont, Westmoreland county, Pa.

TORBERT—COOK.—January 6th, 1882, at the residence of the bride's parents, by Rev. P. H. Mowry, Dr. E. G. Torbert, of Driftwood, Pa., and Kate S. Cook, daughter of Jesse Cook, of Philadelphia.

DEATHS.

HASBROUCK.—In New York, on Wednesday, December 28th, 1881, Stephen Hasbrouck, M.D., in the 88th year of his age.

KNOWLES.—At Clifton, Delaware county, on December 26th, 1881, Henry B. Knowles, M.D., aged 22 years.

SHEARER.—At Dillsburg, Pa., December 14th, 1881, James M. Shearer, M.D., in the 48th year of his age.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

CLINICAL CASES OF SURGICAL DISEASES OF WOMEN.

BY ROMAINE J. CURTIS, M.D.,
Of Joliet, Ill.

Restoration of the Perineum.

Case 1.—Mrs. ——, aged twenty-six years. Three years before I saw her, this lady was delivered of a hydrocephalic child—a still birth. The feet presented, and forceps were applied to the head, effecting its delivery, with the result of producing a complete laceration of the perineal body, and of the septum through the sphincters. From date of the injury this lady experienced the usual sequent miseries of this injury. She had no voluntary control over the sphincter function of the bowel, and had prolapse of the bladder. She was confined to the house, and generally to the bed. During this time she lost weight and color, and began to cough, and had chills and night sweats. Her mother having died at an early age with consumption, this disease was reasonably feared by the patient and her friends, in her own case. I was called to see her on account of her lung disease, and found a condition of her right lung which, I believed, indicated fibrous phthisis. She told me nothing about her injury until the fact was developed by inquiries relating to the uterine organs. On examination, I found the condition as stated. I advised the patient to have the perineum restored by operation, and afterward to take a trip to Colorado, for her lungs, to which she and her friends assented. In the surgical treatment of this case I followed the method practiced and advised by Dr. T. H. Emmett in his truly great work on gynæcology. As a preparation, locally, for the operation, vaginal injections of hot water were used daily for about two weeks, and sesquioxide of iron was given internally.

On the fourth day before the operation a laxative was given, which was repeated daily, the last dose being given the evening before. The intestines were as empty as they could be made, which plan is most decidedly a great improvement over the old one of giving a cathartic only the day before the operation. At six o'clock in the morning two grains of opium were given, and at nine o'clock the operation was performed.

The patient took ether very kindly, and when under its influence I removed the cicatricial tissue and as much of the vaginal mucous membrane as was deemed necessary. The rent in the septum was so great that the apex of the denudation in the mucous membrane was well up in the *cul de sac* behind the cervix. During this part of the operation the bleeding was excessive, several vessels being cut, and the capillary bleeding being greater than was expected after the prolonged use of hot water. I have since learned enough to know that the sesquioxide of iron contributed to this result, as it inhibits the vasomotor contractors, and I have lately used it in angina with better success than is given by nitrite of amyl. To control the bleeding, hot water was used by one of the assistants, at first with a sponge, and then with a syringe. The two physicians who assisted in the operation and I, soon learned to keep a stream of hot water following the cut of the scissors; but for this the operation would have been almost impossible. The

surface denuded was unusually large, and eight silver sutures were used. The first suture was placed in that relation to the sphincter which insures its union, and which was demonstrated by Dr. Emmett, and is difficult to explain without the aid of the diagram given in his book.

The last suture was inserted through the vulva and passed through the mucous membrane above the denuded surface, which drew the membrane over the vaginal portion of the surfaces, where union was hoped for. The placing of the lower and upper sutures in this manner, with the object of placing the torn edges of the sphincter in apposition in one case, and of protecting the uniting surface from the septic influence of vaginal biological ashes in the other, are certainly strokes of a gynecological genius.

On the sixth day after operation the two middle sutures were removed; the remainder were removed on the twelfth day, and the union was perfect. Injections were given, to render the contents of bowels soluble, and they were moved without injury. During the twelve days, one-half a grain of opium was given daily, which was sufficient to prevent any action of the bowels, and vaginal douches, carbolized, were also used daily, and the urine drawn twice a day, great care being used to avoid getting any urine into the wound.

The general health of the patient began to mend as soon as she was out of bed. She gained flesh, got a good color, and went to Colorado for six months. The lung disease was subdued, so far as any active manifestation goes. It is now three years since the operation was made; the lady during this time has again become a mother, with very little injury to the perineum, and her health is good.

Case. 2.—Mrs. —, was aged twenty two years when she was delivered of her first child. Her *accoucheur* was a member of the hybrid, homœopathic, "new school" of medicine. The perineal body, as a result of this labor, was torn through, as well as the external sphincter muscle. The sequences of the injury were: A limited control over the sphincter function, and prolapse of the uterus, the cervix of which was somewhat lacerated. The patient attributed her misfortune entirely to the fact that her physician during the bearing down pains kept straining the perineum backward with his fingers. On questioning her, I learned that she was delivered while lying on her left side, with thighs flexed, which position, combined with the efforts of her physician, were certainly proper antecedents to such a calamity.

I wish here to contribute a mite toward the literature of management of the perineum during labor. It is obvious that the perineum serves a purpose in the mechanism of labor, and other things being equal, does not require the support so much talked about in the text books. The benefit of such support—pressure with the hand—having the effect to aid the perineum in giving the head a forward direction, describing a curve around the pubis. It is apparent that if this direction of the head is maintained there is so much less danger to the perineum. The course of the head through the pelvis, in the direction of the curve of Carus, is in great part due to the anatomical conformity of the pelvis; but the office of the perineum is to continue the course of the head in the circle of which the curve of Carus is a segment, and the opposing force to this perineal force is the pubis. It is, then, a deduction from these facts, that support of the perineum means aiding the perineum to continue the course of the head in the direction of a circle which is continuous with the curve of the pelvis. It is a further deduction, that straining the perineum in the opposite direction directly interferes with the mechanism of labor, and as directly endangers the perineum. Another factor in the support of the perineum is the position of the parturient woman. It may easily be demonstrated that the woman, when the head is describing the curve around the pubis, should lie with her thighs extended. If the finger of the *accoucheur* be inserted between the head of the child and the perineum, and the woman's thighs are flexed, the tension of the perineum is felt to be greater than when the thighs are extended, other things being equal. If this demonstration proves anything, it is, that flexure of the thighs upon the abdomen increases the curve of Carus very notably in that portion of its course bounded by the perineum, and that flexion of the thighs during delivery of the head and shoulders directly increases the danger to the perineum. I have never attended a parturient woman who suffered rupture of the perineal body to any notable extent, which fact I attribute to the reason that I discovered the facts as given, relating to flexion of the thighs and tension of the perineum, in the third case of labor which I attended, sixteen years ago—a primipara, thirty-eight years of age, during whose labor the head remained two hours in a position which partially distended the perineum. This discovery, I suppose, has been made by many physicians, but I never happened to see the record of it.

In this case the operation for restoration of the

perineum was made by the older method. Instead of cutting away the cicatricial tissue and the mucous membrane, the epithelial tissue only was removed and the silk quill suture used. The union was not as complete as in Case 1. To all appearance, as manifest to touch, the perineal body was intact; but a communication existed between the vagina and external perineum, along which water could find its way when injected into the vagina. The patient, however, was cured, by the operation, of the prolapsus and the inconvenience relating to the bowel.

Restoration of Cervix.

Case 3.—Mrs. —, when I saw her, in February, 1880, was forty-two years old and the mother of five children, the youngest seven years of age. This lady is a native of England, and her physician in London was the famous Dr. Richardson. I was called to see this patient on account of an attack of menorrhagia. I made no examination, as the proposition to do so was thought by her to be unnecessary, as she stated these attacks had been repeating themselves at intervals during the last two years, and she thought they were due to approaching change of life. I prescribed large hot water vaginal injections and a preparation of ergot and digitalis, to be taken in a decoction of cinnamon.

In two weeks I saw patient again, and was obliged to use the tampon. I discovered, by digital examination at this time, that she had a complete laceration of cervix. I found it necessary to tampon vagina several days, and learned by repeated examinations that the cervix was split entirely, and its lateral halves were, so far as could be determined by touch, continuous with the vaginal walls. I confess that I was nonplussed by the case as felt at first, for, sliding my finger up the vaginal wall, I would find no evidence of a cervix, or Douglas *cul de sac*, but my finger would pass up into the cavity of the uterus, which fitted it like a cup thimble. I had never seen a laceration so extensive, and was unprepared to know the meaning of the tactile sensation. I became satisfied, however, what the condition of things must be, and in a few days, the bleeding having ceased, I made an examination with Sim's speculum, and found that I could see the fundus uteri, as well as feel it, there being no external or internal os. With two hooks I brought the halves of the cervix from, apparently, out of the vaginal walls, and drawing them together the form of the uterus could be seen. The perineal body was also lacerated, and the fundus of the uterus—the inside of it—was about two inches above the vulva. I explained the nature of things to the patient, who remarked that Dr. Richardson said she was ruptured, and had proposed an operation to relieve her before she left London. The cervical mucous membrane was congested, and pricking it let out an abundance of gelatinous substance.

I told the patient that her life depended on the restoration of the cervix, and two months were occupied in the preparatory treatment and unavoidable delays. The treatment consisted in administration of ergot, digitalis, and dialysed iron; a daily vaginal douche of a gallon of hot water, and application every third day of compound tinct. of iodine to the cervical membrane and uterine cavity. There were frequent and severe hemorrhages during this period of preparation, and for twenty days, in the aggregate, I was obliged to use the tampon. A notable feature of this treatment was the hot water injections, which were performed with the ordinary Davidson's syringe, using one gallon of water at once, and which was, of course, injected directly into the uterine cavity, without a symptom of the usual uterine colic which follows sometimes the advent of a small quantity of water into the uterus. There was apparently no more sensation, in character or degree, in this patient's uterus than was afforded by the vaginal walls. The patient could distinguish her menstrual hemorrhage from other paroxysms of bleeding by the backache and other sympathetic pains, and the operation was appointed on the fifth day after accession of menses, providing the flow could be stopped. At next menstruation she was tamponed, as usual, and seven days passed before she was ready. At this time a physician sent her word that he could cure her without an operation, and in consequence the operation was delayed until ten days before the time for her next menstrual period. The operation was made as Emmett directs: the cicatricial and mucous membrane being removed, leaving a space for the cervical canal, the two halves were brought together, and eight silver sutures were used. On the fourth day after the operation she began to flow, which I supposed would destroy the hoped-for result of the operation. The flow continued about six days. I left the sutures in place fourteen days, hoping union might occur, when the patient had an attack of winter cholera, which came on at night, was very severe, and when I reached her she was collapsed, almost pulseless, and was, to all appearances, a hopeless case. Her family and friends were around her in the attitude of mourners, and I never saw so pale and exsanguined a surface

as she presented. I gave her, hypodermically, morphia sulph. gr. $\frac{1}{8}$ and atropia sulph. gr, $\frac{1}{20}$, the remedy which I relied on for winter cholera. She began within an hour to rally, and recovered from the attack. She was plied with beef extract and brandy until the eighteenth day from date of operation, when I removed the sutures, fully expecting to see the parts separate, but to my great surprise the union was perfect. At her next menstruation the patient declared she was "more natural than she had been at any time since she was twenty years old." She has been healthy ever since and has gained thirty pounds in weight. The uterus occupies the normal position in the pelvis, notwithstanding the perineal body is gone.

Case 4.—Mrs. —, was married at the age of thirty-eight years. She was small in stature, light in weight, had always been a subject of neurasthenia, with neuralgic manifestations, but never had any of the zymotic diseases, or acute sickness, and yet says she never had a well day.

Within a year after her marriage this lady was delivered of a ten pound boy, by aid of forceps, and the cervix was completely lacerated. In this case the split was not midway in the cervix, but the anterior portion was about half the thickness of the posterior. The two sides rolled out, after the manner of a celery root when split in the axis of its length. The laceration extended upward on the external surface of the cervix to its junction with the vaginal walls, and internally extended through the internal os. The sequences of this injury were entirely referred to the nervous system, and the only discomfort was neuralgia, which appeared to extend throughout the whole sensory nervous system connected with the pelvis. The pain was nearly constant, and confined her to bed. Sleep could only be procured after great exhaustion from wakefulness and suffering, or by chloral. At the end of the second month the cervix was restored by the same method as in the previous case, but without an untoward symptom. The sutures were removed on the tenth day and the union was found perfect. The restoration of the cervix cured the pelvic neuralgia, and her general health is much better than before her marriage.

Case 5.—Mrs. — was twenty-eight years old when she was delivered of her first child, by forceps, with the lamentable sequence of unilateral laceration of the cervix and complete rupture of the perineum. Her physician told her that the accident was due to the fact that the child had no soft spot in its head. I suppose he referred to the condition of the fontanelles. He, however, immediately inserted silver sutures, and to all appearance the perineum was united, and the medical gentleman assured the patient that the like was never known before. I saw the case three months afterward. The patient was emaciated, had loss of appetite, indigestion, and the urine loaded with phosphates. She referred her local distress to the bladder, stating she not only had difficult micturition, but could not sit, except on one of the nates, or rather one hip, frequently changing from one side to the other, on account of painful sensations produced in the bladder.

On examination, I found that the perineal body was not united, but there was a union of the integument of the perineum, which bridged across the chasm, and somewhat resembled the web of a goose's foot. The uterus emitted a discharge of acrid, purulent matter, and was prolapsed, resting between the severed halves of the perineal body. To relieve the sensation of bladder distress I cut the bridge away with scissors, which allowed the patient to sit upright, by removing the tension from the integumentary perineum, and proceeded to prepare her for restoration of cervix and perineal body. These operations were completed in due time, without misfortune or hindrance, and the patient recovered her health. She has since given birth to her second child, during the labor for which the perineum remained intact.

Case 6.—Mrs. —, when I saw her, was aged nineteen years; had been married three years; and a year since gave birth to a child. Since then her health had materially deteriorated. She was subject to hystero-epilepsy, and was at times quite maniacal. There was a bellows murmur, heard loudest over the apex of the heart. She never had rheumatism She complained of an acrid vaginal discharge, which caused great irritation, and had been treated for ulceration of the cervix, without benefit. I detected a unilateral laceration of the cervix by digital examination, there being so much vaginal inflammation that I could not use a speculum. She was directed to use hot water vaginal douches, and returning in two weeks, a speculum examination was made, which verified the existence of the laceration. The lacerated surfaces were secreting pus of an acrid character, which kept the vaginal mucous membrane in a condition of inflammation. Topical applications of the comp. tinct. of iodine were made daily to the wound, and punctures with a sharp lancet as often, to let out the gelatinous matter. The parts appearing ready for the operation, the day was

appointed, but while getting ready, owing to excitement, the patient had an attack of hystero-epilepsy, which postponed matters. This occurred the second time, when I adopted the strategic move of making the operation without foreknowledge on her part. The patient was placed, as usual during her local treatment, in Sim's position. I quickly denuded the surface, but trouble began in patient's head before I could insert the sutures. I took a cup pessary, and applying it over the cervix, packed the vagina with a cotton tampon, fixing thereby the stem of the pessary. The patient was accustomed to applications of cotton glyceroles, and with additional persuasion became quiet. The next day she was informed of the condition of matters, and remained quiet in bed. Every other day I removed and replaced the cotton tampon, carefully keeping the cup pessary in place by holding the stem. This procedure was kept up for ten days, when I ventured to look at the cervix, and had no reason to be dissatisfied with the result. The surfaces were united. The patient was put on increasing doses of bromide of zinc, which, together with a change of climate, worked a cure.

SOME POINTS IN REGARD TO TROPHIC NERVE CELLS.

BY J. S. WIGHT, M.D.,

Professor of Surgery at the Long Island College Hospital.

Written for the MEDICAL AND SURGICAL REPORTER.

(*Concluded from p.* 64.)

Let me reason from our premises a little further: Is not the molecular motion in the cells of a muscle transformed into the molar motion of the bone to which it is attached? But these muscle cells received molecular impulses from nerve cells by the way of nerves. Now, suppose that the cells of a muscle are so arranged that their molecular motion cannot, as it were, be added up into a visible motion; then there would be simply molecular motion in the muscle. And because the molecular motion is invisible, can we conclude that such motion does not exist? And can we say that such motion, if it does exist, has no relation to nutrition? We might just as well say that heat has nothing to do with nutrition, when we know that nutrition stops without heat. But our supposition exactly fits the case of any cell that is not a muscle cell. That is, a nerve cell may be co-related to a cell, and be associated in the work of making simple molecular motion in that cell; that is, a motion that does not eventuate in molar motion; and, from all that we can know, this molecular motion is intimately concerned in the process of nutrition.

Now, let it be assumed that a Pacinian corpuscle envelops the end of a single nerve, and that the nerve has a sensory function. It is true, that the end of this nerve is enclosed, at times, by as many as sixty capsules, made up of a great number of fusiform cells, which, to some extent, resemble the cells of the connective tissue. There are two points to be noted in regard to these envelopes of a Pacinian corpuscle: (1) As the nerve end seems to be concerned with the sense of touch, the mechanical influence of an impinging body is transmitted through the fusiform structure of the capsule to the nerve end, and correlated into a motion that can go along the axis cylinder of the nerve to the nerve cell at the other end of the nerve. Indeed, the conditions here are somewhat like the conditions relating to the cornea. The cornea is transparent to a certain kind of molecular motion, and the Pacinian corpuscle is transparent to a certain kind of mechanical motion. The fibrils of the nerve are in a bundle in the Pacinian corpuscle; the fibrils of the nerve are separated in the cornea.

(2) It is quite evident that the nerve cell at the other end of the nerve, through the nerve which penetrates the Pacinian corpuscle, as it were, presides over the multitude of cells that go to make up the investing layers of this capsule. That is, there is a very considerable territory of cells, in some way coördinated with a single nerve cell. And, in regard to this coördination, it would make no difference whether a sensory or a motor nerve penetrated the Pacinian corpuscle; break up this coördination, and the nutrition and the function of the part would be disturbed. And in regard to the cell territory, it more and more appears that the destiny of nerve cells is to preside over such territories. But there are certain *possible* exceptions to this relation, which may be intimated as follows, namely:—

(1) In the early life of the embryo, so far as we now know, there are no nerve cells—surely there are no nerves; the cells appear to be all alike; and yet there are cells that are destined to be nerve cells, or the antecedents of nerve cells, and have nerves. But yet is it not a matter to be considered, that the primitive cells of the embryo are in some way co-related to the complex nervous organism of the mother? Who does not know about the strange results to the embryo coming from disturbances of the maternal nerve cells? Can we then say with confidence

that the cells of the embryo are nourished and proliferated without the intervention of nerve cells and nerves? Note in this connection, the extraordinary development of the peri-uterine sympathetic system during pregnancy. It seems to be the fact, that the cells of the embryo constitute for a time a kind of outlying territory, that is still under the domination of the maternal nerve cells, in an indirect manner. Well, if these things are so, our first exception is not a real exception.

(2) In the blood there is the most active nutrition going on constantly, and yet there is no anatomical connection between the nerve cells and the blood cells. But there is a dynamic relation at most times between the blood cells and the nerve cells, as well as other cells in various parts of the body, and the nerve cells would not get along without the blood cells, any more than the blood cells would get along without the nerve cells.

We may, therefore, truly look upon the blood as containing a community of cells, which are not continuous with any nerves in an anatomical way, but which are related to nerve cells, and we may affirm that there is a correlation of energy constantly going on between these two kinds of cells. And so far, indeed, as respects the blood, do the nerve cells have a trophic function.

(3) In *granulation tissue*, where, to be sure, we do not find nerves, there is a remarkable activity in the elements of the protoplasm, in which not only nutrition, but also proliferation is taking place. And I may ask, who is ignorant of the fact that granulation tissue is apt to form either badly or not at all, in paralyzed parts? Are not the tissues on which granulation tissue begins to form full of nerves? And is not granulation tissue very often tender and painful? Well, very briefly let me say, that granulation cells and nerve cells are not only co-related, but they are also correlated. The granulation cells constitute an outlying cell territory, that we may in some sense liken to primitive embryonic tissue. And yet the granulation cells have the capacity to be affected by the influence of that most highly differentiated cell—the nerve cell. And this means, that the trophic powers of the nerve cell are concerned with the *trophic* powers of the granulation cell. Let me add, that what has just been said of young scar tissue may also be said of adult scar tissue. And so again, if these things are so, our second and third exceptions are apparent and not real exceptions.

And in this connection let me say, that the formation of granulation tissue in parts that have lost sensation and voluntary motion takes place, in all probability, under the constructive influence of the ganglionic nerve cells, as well, perhaps, as under the influence of integral spinal cells below the pathological severance of the cord. In the next paragraph a case will be introduced that will illustrate this interesting point.

The following case of fracture of the dorsal spine is quite fully reported on page 799 of the American edition of "Holmes' Surgery." A shoemaker, twenty-four years of age, fell from a second floor window, broke his back near the middle, causing loss of motion and sensation in both lower extremities, and in a little more than four months recovered, except there was a defective sensation in a small part of the right leg. For seven years he was well and active; in the next year he had a fever, and a pain in the back; for five years more he continued in good health; he then began to have progressive paraplegia, and finally was bed-ridden, having extensive sores on his hips. The sacrum, ischia, and trochanters were foul and sloughy to a great depth, and did not cause any pain. Diet, stimulants, quinine, opium, and a water-bed, gave the patient considerable strength. The bed-sores, which were dressed chiefly with the balsam of Peru, filled with healthy granulations, and cicatrized as quickly as in the soundest constitution. Near his death, which followed extreme exhaustion, he had profuse perspiration on the parts of his body that were not paralyzed.

The post-mortem examination disclosed a fracture of the fifth dorsal vertebræ; a degeneration of about two and a half inches of the cord; an obliteration of the corresponding nerve roots; and the upper and lower parts of the cord held by connective tissue and the pia mater.

In this case may be noted some interesting points:—

(1) The nerve cells of a considerable part of the cord were disintegrated. It would seem that the nerve cells did not inflame, nor proliferate under the stress of a prolonged irritation. Indeed, there was no repair of nerve structure and no restoration of nerve function; for when the nerve cells perished no new nerve cells took their place. And it appears that highly differentiated cells have not the same ability to proliferate as the cells of the connective tissue.

(2) Some of the original connective tissue remained in and around the obliterated part of the cord, and some new connective tissue was added thereto, as it were, in the form of scar-tissue. *Here there was inflammation and proliferation as well.* And we may note the difference between

the connective tissue and the nerve tissue under the influence of an irritation. The connective tissue cells live and increase in number, and the nerve cells perish; and may we ask, *Which cell is the fittest to survive?* In fact, the cell that survives is the one of lowest differentiation.

(3) But, as Brown-Sequard and M. Charcot would say, the point of capital importance was the irritation, or the inflammation, that supervened in and around the cord. The irritation and the inflammation were connected with the bed sores; but how were they connected?

During a long time the nerve cells of the injured part of the cord did good work; but during a long time, the time of progressive paraplegia, the nerve cells of the injured part of the cord did imperfect work. Now we may suppose that in the degenerating spinal cells there was an irritation which was communicated in some way to the cells of the sympathetic ganglia and to the cells of the cord below the injury; and we may infer that there is an irritation communicated to various cell territories to which certain nerves are distributed—an irritation coming from the degenerating nerve cells of the cord, and from the disturbed nerve cells of the sympathetic ganglia and the cord below the injury. In fact, there was a disturbance of the normal coördination of work between the nerve cells of the ganglia and the cord; and there was a disturbance of the correlation between the nerve cells of the ganglia and the cord on one hand and the cells of certain outlying territories of the body on the other hand, so that many of these cell territories perished. But the most significant part of this case, perhaps, consists in the fact that the bed sores went through a most laudable process of cicatrization after the complete degeneration of the cord for about two and a half inches, and during all this time the patient was approaching his death step by step. There was a complete structural and functional severance of the cord, but the sympathetic ganglia remained intact. And we may suppose, in the most reasonable manner, that the nerve cells of the sympathetic ganglia continued to do good work after they were no longer irritated by the degenerating nerve cells of the cord; and we may also suppose that the nerve cells of the lumbar enlargement of the cord performed some laudable work after the death of their neighbors in the cord above. In fact, we may suppose that the nerve cells which were left performed their own work as well as they could under the circumstances, and may be, tried to perform the work of the degenerated nerve cells. And yet, it may be remarked that, though the scar tissue seemed to form well, there was something radically wrong in the nutrition of the cell territories in general, for the coördination of the cell work of the body was so far disturbed that the nutrition could go on no longer.

In this case there was finally a total loss of sensation and voluntary motion, which, as a matter of course, had something to do with the derangement of the nutrition. And in this place the attention may be fixed for a moment on the fact that the sweat glands had lost their function below the seat of the injury, and that above the seat of the injury they had come to have a very exaggerated function. In what way this disturbance of the sweat glands took place it is only possible to conjecture; however, the disturbance relates to the nutrition. But yet it would seem competent for us to conclude that the irritation of the nerve cells of the sympathetic ganglia had very much to do with the production of the bed sores, and that, when this irritation had ceased, the bed sores cicatrized under the influence of healthier nerve cells.

(4) Let me point out what I have often observed in fatal cases of spinal injury, that the nutrition of the parts paralyzed is so deviated from its normal procedure as to be competent to give off abnormal waste products, which will impede the proper nutrition of the parts above the seat of the injury. There is, as it were, a kind of degeneration going on in the cells of the parts that have been paralyzed, and death at last takes place, mostly from extreme exhaustion and a kind of septic poisoning. At any rate this goes to show that the cells of the sympathetic ganglia, whatever their function, have, indeed, a coördinate relation with the cells of the cord; and that the sympathetic cells cannot do their work properly apart from the spinal cells; and that the spinal cells cannot properly carry on their functions without the aid of the sympathetic cells.

In fact, it may be set down that there is not only a co-relation, but also a coördination between the cells of the spinal cord and the cells of the pre vertebral ganglia, and that special cells perform special work, and that some of the special work performed is *trophic* work. And it may also be set down that there are special ganglia co-related and coördinated, not only with the pre vertebral ganglia, but also with the gray matter of the cord, such as the semilunar and renal ganglia, as before noted, and that these ganglia have also special work, some of which work is indeed trophic in its nature. And so we

surely arrive at the conclusion that the *trophic nerve cells* are not all in the gray matter of the cord, but that some of these cells are to be found in the gray matter of the sympathetic ganglia. We also arrive at the conclusions, that in the correlation of some nerve cells and muscle cells molecular motion eventuates in molar motion, and that in the correlation of some nerve cells and certain other special cells, molecular motion continues to be molecular motion. And the fact that we cannot see the motions of nutrition, and that we can see the motions of progression, does not prove that the motions of nutrition do not take place, and that these motions are not in some way correlated, in part, at least, to the *energy of nerve-cells*. Indeed, the convertibility of molecular and molar motions, and the analogies between special cells of the body, ought to lead us to the view that the work of the nerve cells and the work of cell territories are intimately associated, no matter what the uses are to which protoplasm may be put.

In fine, conclusions may be reached, that it is not quite correct to speak of *trophic nerves*, while it is more correct to speak of *trophic nerve cells*; that the trophic nerve cells are not all found in the gray matter of the anterior horns of the cord, but that some of the trophic nerve cells are found in the ganglia of the sympathetic. In a word, the nerve cells of the cord and the nerve cells of the sympathetic ganglia coöperate, as the cases above noted indicate, in the work of nutrition. A great many cases might be brought forward whose evidence would tend to the same conclusion. But I have already written enough to direct attention to a subject of capital importance—*and that is, the* general *coördinate and inter-dependent work of all the special cells of the body.* And I may only add, that it would take up too much time and space at present to write anything on the trophic relations of the nerve cells of the brain.

Hospital Reports.

UNIVERSITY HOSPITAL.

CLINIC OF LOUIS A. DUHRING, M.D.,
Professor of Dermatology.

Reported by Louis J. Lautenbach, M.D.

TINEA TONSURANS; SYPHILITIC GUMMA; PAPULO-SQUAMOUS SYPHILODERM; VESICO-PAPULAR ECZEMA.

Tinea Tonsurans

This little boy has been brought to the clinic by one of the students. He comes from a neighboring town, with a disease of the scalp. The first thing that we notice is that his hair has been clipped. He is about eight years old, fairly nourished, and has light hair; he is spare and has the general appearance of a strumous disposition. He probably cares little for meats, or fats of any kind; he says that he never eats fatty food.

Examining the disease, we observe that it occupies the greater part of the scalp, in the form of a good deal of scaling, which has been plastered down by ointments; in addition, we see signs of the disease in the form of irregularly rounded patches, which are somewhat bald. Over the occipital region we have the outline of quite large patches, which have coalesced. The disease, from its appearance, has probably lasted for six weeks or longer. He says it started three months ago. Looking more carefully, we see that the hairs are partially destroyed on the patches. In addition to the patches being bald, the orifices of the follicles are puckered, the skin looking like that of a plucked goose. This appearance is pathognomonic of ringworm of the scalp—tinea tonsurans.

Examining the disease more closely, we see a number of stumpy hairs, which can be easily plucked out. Placing these hairs under the microscope, we shall observe that they are thoroughly invaded by the parasite. The patches of baldness are more or less irregular in outline, and in the parietal region we observe the hairs thoroughly "nibbled off" by the parasite.

The diseases with which we are likely to confound it are seborrhœa and squamous eczema. Considering the partial baldness of the patches, the stumpy, loose hairs, and the presence of the parasite, there is no difficulty in diagnosing the case from eczema. From seborrhœa it can be diagnosed by the fact that the hairs are nibbled off, and destroyed, while in seborrhœa atrophy occurs. Again, in seborrhœa we have simple epithelial and fatty degenerated scales; here we have not only the scales, but also the hairs invaded by the parasite. The diagnostic aid which the microscope gives us is often of great importance, and no one can work in this branch of medicine without its valuable assistance.

The disease is common in children's asylums, and it is here that the worst cases are seen. Once having found its entrance, if not energetically treated, it will rapidly spread, until perhaps 20 or 40 per cent. of the inmates have the disease. The treatment in such cases is difficult.

In all cases there are two lines of treatment to be observed: depilation, or the extraction of the hairs, and the use of a parasiticide; being careful, however, not to use too strong ointments or solutions, lest you cause undue inflammation. The disease is treated somewhat differently, according as it occurs on small or large areas of surface, in the latter case being more difficult to cure.

As parasiticides, the sulphur preparations are all valuable, in the form either of ointments or solutions. In this case we cannot do better than order sulphurous acid. Before applying this, we will direct the scalp to be cleaned with warm water and soft soap twice a day, after which the acid is to be used by dabbing it on with a soft rag, it being diluted at first with two or four parts of water, increasing the strength until it is used pure. If the skin, during our treatment, becomes dry, we may combine with other treat-

ment the use of cosmoline. Besides this, depilation must be practiced, the loose hairs being removed by the forceps.

Another remedy which is sometimes used is corrosive sublimate; it being employed of the strength of from one to five grains to the ounce of water or alcohol. It is, however, liable to be absorbed and to produce constitutional symptoms, especially if applied to large surfaces. Such cases have been reported, and one case where the use of a ten-grain solution was followed by death. I must say, however, that I have never seen any cases of this kind.

The disease is liable to relapse, and even when it appears to be perfectly cured it is best to keep on for several weeks with a mild parasiticide. To illustrate the liability to relapse, I need only mention that a similar case to the one before us was brought to me a few years ago, which three or four times I thought entirely well, and yet each time but the last, when he was perfectly cured, he was brought back to me with a return of the disease. This shows that you should not pronounce such a case well until a month or two after the entire disappearance of the disease.

There is no danger of the adult contracting tinea tonsurans; but there is great danger of children contracting it. Male adults are, of course, liable to contract tinea sycosis, which, as you know, is due to the same fungus—the tricophyton.

Syphilitic Gumma.

This colored man, aged 25 years, comes with the history that he has been under treatment for syphilitic disease of the skin, and that he recovered, and that he now has a tumor the size of a half walnut situated over the upper part of the sternum. The tumor is slightly red, illy defined in outline, and has a fluctuating feel. If we ask him how long he has had it he will probably say that it has existed two or three months: the latter period he says is correct.

We have here a typical syphilitic gumma, in which the process of breaking down is now occurring. He says it has been painful, but that it is not now so, unless pressed upon.

The only disease that we are likely to confound this with is simple abscess. It is quite common to find gummata in this situation. If he is put under treatment it may either be absorbed or it may rupture; it is difficult to say which, but I am inclined to think, nevertheless, that it will open.

We will put him on potassium iodide, ten grains, and gradually increase to twenty grains, three times a day. In three or four weeks we will put him on potassium iodide, five grains, and the bin iodide of mercury, one-sixteenth of a grain. This preparation of mercury is, I think, more satisfactory than corrosive sublimate; as a rule it agrees better with the patient.

Papulo-Squamous Syphiloderm.

This man, aged thirty, comes to us with a disease of the skin which has existed six weeks, and for which he has been under no treatment. Flat patches and papules slightly scaly occupy the forehead and face, the lower extremities and the forearms symmetrically, the scalp, and the back of the neck. The disease invaded all parts of the body at the same time, all within a week, and has been getting worse steadily.

In endeavoring to make a diagnosis we naturally think of two diseases, viz: psoriasis and the papulo-squamous syphiloderm. He has never had any disease of the skin before, nor has he, he states, ever had any venereal disease.

If a syphilitic eruption, it might have come on at any time after the second or third month subsequent to the chancre or initial lesion, but it usually comes on much later. The glands now are not involved. He has, however, he says, sore throat, which came on shortly before the appearance of the eruption.

Here, on the leg, we see the characteristic, syphilitic moist papule. It is sharply defined, has a glazed surface, with a central depression marked by considerable induration; it gives the diagnosis at once. Now we look for infiltration, because in the syphilitic papule there is more infiltration than in papular psoriasis. On the forearm we also see flat papules, with a tendency to break down in the centre.

We have here, then, a case where the man denies all knowledge of the primary lesion, and yet it is surely a case of papulo squamous syphilis. To distinguish this from psoriasis, we have the fact that the infiltration is here more marked; the papule is more circumscribed and is more papular; and there is a tendency to depression in the centre, which shows the destructive metamorphosis. The lesions, indeed, are often difficult to diagnose from psoriasis. The man should be told of his disease, and what can be done for him in the way of treatment, and he should also be informed of the probable effects of the disease if not properly treated.

Vesico-Papular Eczema.

This young man was sent here from a neighboring town, with a history of a chronic disease of the skin, which, when first seen, was diagnosed as chronic eczema. It occupied the thighs, legs, feet, back, forearms and hands. As you see, he is pale and anæmic. To-day all the lesions are so improved that the former disease is scarcely to be recognized. On the back, however, we observe broken down vesicles in the form of a patch. On the shoulders the disease is more marked, and in the form of vesico-papules. Accompanying the disease there is a great deal of itching. Three or four days ago various sized pustules, now scarcely to be observed, were present. The case is both an interesting and a serious one. The disease first appeared three years ago, in the same form, on the arms. Some weeks afterward the disease repeated itself on the hands, since which time it has been getting "better and worse." For the last six months it has been getting steadily worse, and last month it was very bad, the itching being intense, not allowing him to sleep.

Coming now to treatment: At first we used the "liquor carbonis detergens," a solution of coal tar in alcohol, used in the strength of a ʒj to ʒj ij of water. This was applied to relieve the itchir ɣ. After ablution with this, he was anci ed with oxide of zinc and petroleum ointmc 'qual parts. Internally he took tr. ferri

chlor. gtt. x, and quinia sulph. gr. ij, three times a day. Later, as he was not much better, he was ordered ung. picis et ung. petrolei, equal parts. The next day, as he was markedly worse, it seemed evident that the ointment did not suit him, when he returned to the first line of treatment, and he has since improved considerably. In order to procure sleep, we have been using chloral gr. xv, et potass. brom. gr. xx.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, January 5th, 1882. The President, Dr. E. L. Duer, in the chair.

Dr. Wm. Goodell reported the following case of

Extra-uterine Fœtation.

Mrs. B. C., aged thirty, had been married two years without conceiving, but on March 19th her catamenia ceased, and she deemed herself pregnant. She now began to suffer very much from nausea and from pelvic pains, for which her physician, Dr. W. C. Parry, of Mount Holly, New Jersey, was in attendance more or less after May 6th. On May 16th, while ironing, she was suddenly taken with a violent colicky pain in her right groin, accompanied by a vaginal flow of blood and by collapse. These colics lasted off and on up to July 15th, when she felt relieved. Dr. Parry had meantime discovered a pelvic tumor on the right side of the womb, and had diagnosticated extra-uterine fœtation. But from September 5th to 13th she had great bearing-down pains, like those of labor, attended by some hemorrhage. The cervical canal dilated sufficiently to admit the finger, a miscarriage seemed imminent, but nothing was thrown off. This threw the physician off his track, and he renounced the idea of extra-uterine fœtation for that of natural pregnancy. She had felt fœtal movements, but from this time the child was still, and milk appeared in the breasts.

Her health now began unaccountably to fail, she lost flesh and strength, and became bed ridden. During the first week of last November she had another hemorrhage, with labor-like pains, and the cervical canal and os-externum again dilated during the disturbance. From this time she began to fail very rapidly, having chills, a high temperature, a frequent pulse, and quick emaciation. On November 15th I was called in to see her. On account of the excessive tenderness of the parts, ether was given. An irregular tumor occupied the abdomen, but smaller than the uterine globe at eight months' gestation: neither fœtal limbs nor the fœtal outline could be felt, nor could the presence of any fluid be made out. The cervix uteri was in a natural position, quite hard, and with a small os-externum. The sound passed in five inches, and to the left. No fœtal sounds or uterine murmur could be detected. My diagnosis was a guarded one, but leaned to an extra uterine gestation.

On November 24th, aided by Dr. B. F. Baer, of Philadelphia, and Drs. W. C. Parry, A. E. Budd and R. E. Brown, of Mt. Holly, I performed the operation of laparotomy. As soon as the peritoneum was cut open an adventitious cyst was exposed. I perforated it with a probe and enlarged the opening with a uterine dilator. Finding that the placenta covered the whole lower three-fourths of the sac, I prolonged the opening upward and removed the fœtus. It was macerated and had been dead some time, as the flesh over the ribs was stripped off during the process of extraction. The placenta was now very slowly and carefully stripped off without any hemorrhage; every preparation had been made to meet one. Not any liquor amnii was present. The sac was then thoroughly cleansed with a carbolated solution, and every antiseptic precaution taken. The opening in the sac was stitched to that of the abdomen; a glass drainage tube put in and the wound dressed with salicylated cotton. Up to December 9th, everything went well; the wound united perfectly, the stitches were taken out, the temperature had fallen, and the drainage tube was about to be removed, when, near midnight, she very unaccountably went into convulsions; these recurred and she died comatose on the morning of the 12th. Albumen was found in the urine, and at an autopsy, the kidneys were found to be diseased. The fœtal sac had become obliterated, and no relation whatever could be discovered between the condition of extra-uterine fœtation and that of the kidneys which carried her off: the latter seemed to be an accident, and in nowise related to the former. From the history of this case, there is no question in my mind that the operation of laparotomy for extra-uterine fœtation must be far more successful after the death of the child. For when the child is living it would, on account of the inevitable hemorrhage, be unjustifiable to remove the placenta; and the presence of so large a mass, which must slough off and putrefy, will seriously compromise the life of the woman. But when the child has been dead for some time, the placenta can be safely peeled off, and the sac be wholly emptied, as in my case.

Dr. Goodell also reported

A Successful Case of Hysterectomy.

The patient, a mulatto of thirty-five, had cystic degeneration of each ovary. The pelvic and intestinal adhesions were of the most formidable character, making in themselves a long and a bloody operation. But in addition to these complications, each ovary was so incorporated with the womb that he was obliged to remove that organ. This he did by dissecting off the bladder, by applying the wire-clamp at a point midway between the os externum and the os internum, and by transfixing the stump with two pins. Strange as it may seem, on the fourth and fifth days quite a smart menstrual flux, or rather a metrostaxis, took place from this small cervical fragment. The clamp fell off on the fourteenth day, leaving a very large and deep funnel-shaped opening, which is now rapidly filling up. It is now three weeks since the operation and the patient is convalescent. He stated that ovarian tumors are rare in the colored race; this being the second case only which he had seen. On the other hand, fibroids of the womb and fibro cystic

tumors are more common with them than with the white race.

Dr. B. F. Baer exhibited a

Monocyst, probably of the Ovary, but which contained Limpid Fluid.

M. J. T., aged forty; single; catamenia regular. In October, 1880, she discovered an abdominal tumor in the centre of the hypogastrium. She has been growing thin in flesh with the growth of the tumor. It apparently has varied in the degree of tension, being sometimes more flaccid than at others. Physical examination revealed a cyst of the abdomen, not very tense, extending one handbreath above the navel; the coronal resonance was very marked; dullness on percussion was also marked, and there was perfect fluctuation throughout the tumor. The womb was movable, flexed to the right, and lay behind the tumor. The sound passed three inches.

From the flaccidity of the cyst, I was at first inclined to believe it to be a cyst of the broad ligament; but the rapid growth of the tumor, and the quick emaciation of the patient pointed rather to an ovarian cyst.

On December 31st, 1881, the tumor was removed by Prof. Wm. Goodell. It was found to occupy a position to the left of the uterus, and was at first thought to be a cyst of the broad ligament, for the following reasons: It was a thin-walled monocyst, and contained a perfectly limpid fluid. The fallopian tube was stretched over the surface of the tumor and elongated; the fimbriæ were spread out on the wall of the cyst. But after a very careful search the ovary could not be found. In a cyst of the par-ovarium the ovary usually occupies a position on the side of the tumor, more or less closely attached to it by a mesovarium. After the pedicle had been ligated, and the tumor cut away, another careful search was made for the ovary, both in the pelvis and on the cyst, but it was not found. The right ovary was found in the normal position and was healthy. The only portion of the cyst-wall which in any way resembles the remains of a degenerated ovary, is a dense white substance corresponding in position to that which would probably be occupied by the ovary; but this forms part of the cyst wall, as the tunica albuginea does in ovarian cystic disease, and there is no sign of an attachment by a mesovarium.

The interest in this specimen hinges on the organ from which it was developed, if it could be proven that it originated in the parovarium, then it is of no special interest, because the arrangement of the external and middle coats allows them to be readily separated from one another, and the fallopian tube is related to the cyst wall in the manner described by Dr. Bantock as peculiar to parovarian cysts; the fluid furnished by it also corresponds to that usually found in such a cyst. But if it is a monocyst of the ovary it then becomes of special interest, for it is denied by several recent writers (Bantock and Tait, for instance), that monocystic tumors ever occur in the ovary, but that when such a cyst is found it is always of parovarian origin. Now that seems to be too sweeping a statement, for many eminent authors, among them Wells, Peaslee, and Atlee, speak of having met with unilocular ovarian cysts, and I can recall a case of a large monocyst removed by Dr. Goodell from a young lady of twenty years, in which the history, the relative position of the fallopian tube to the cyst wall, the close adherence of the different coats to one another, the albuminous fluid, rich in cells, and the absence of the ovary, pointed pretty clearly to ovarian disease rather than to parovarian.

I also present another specimen, which proves beyond a doubt that a monocyst may occur, at least while the cyst is small. This specimen was removed by Dr. Goodell from a lady, twenty-two years of age. It presents a single cyst in each ovary, and in addition a cyst in the broad ligament of one side.

Again, if the specimen first exhibited originated in the ovary, it presented an unusual feature in the character of its fluid, which was limpid and devoid of cells. If it did not spring from the ovary, why could not that organ be found? It could hardly be congenitally absent, when all the organs in its neighborhood, fallopian tube, broad ligament and parovarium, were present.

Dr. Goodell did not consider this cyst one of the ovary, simply because the corresponding ovary could not be found, for one cannot make a prolonged search at such a time. Besides, he had never seen such a clear fluid from an ovarian cyst. Again, another diagnostic point of a broad ligament cyst is the alternations of tenseness and flaccidity. So this cyst was sometimes quite tense, and at others so relaxed as to make it quite difficult to define its outlines. An ovarian cyst, on the contrary, is always tense, even if it has been recently tapped but refilling. Further, the peritoneal and other layers of the wall of an ovarian cyst are so firmly matted together by the cicatrices made by the escape of Graafian follicles that they cannot be easily separated. In this specimen the layers are, like those of a parovarian cyst, very easily torn apart. He himself had no doubt that the cyst is one of the parovarium.

Dr. T. M. Drysdale believed that a thorough search of the cyst might disclose the presence of the ovary, as he had, in several cases of tumor of the broad ligament, discovered the missing ovary spread over and incorporated in the cyst wall. He also considered the limpid fluid, free from cells, an incontrovertible diagnostic point.

Juvenile Alcoholism.

A few days ago a young girl of fourteen died in the slums of this city, under peculiar circumstances. From her earliest childhood she had been accustomed to the free use of the poisonous whisky found in that neighborhood, and became a confirmed drunkard before her twelfth year. One evening lately she attended a ball in the house of a neighbor, and returned home about one in the morning, very much intoxicated. The next morning she was seized with pain in the stomach, vomiting, headache and fever. She grew gradually worse for three or four days, and finally died. A suspicion of poison in the whisky caused the Coroner to make a careful investigation, the result of which was a verdict of "Death from Chronic Alcoholism," in a girl only fourteen years old.

Periscope.

The Causes of the Reduplication of Heart Sounds.

In an article on this subject in the *Medical Times and Gazette*, Dr. E. Sansom says:—

Physiological reduplication at the end of inspiration is accounted for by the fact that the capacity of the pulmonic system being increased, the obstructive burden upon the right ventricle is lessened—consequently the systole of the latter is shortened. The lessening of the duration of the systole of the right ventricle implies anticipation of the diastolic closure of the pulmonary semilunar valves; so there is a reduplicate second sound, the primary element being pulmonic. In pathological reduplication the origin may be in either the right or the left ventricle. If from any cause the systole of one of the ventricles be protracted, the diastolic closure of the valves of its great vessels of exit will be delayed also, and so the second sound will be double.

Guttmann supports the view of non-simultaneous closure of the aortic and pulmonary valves, without giving reasons for the proximate cause. He says, however, that it is not unreasonable to explain it by a change in a single set of the semilunar valves causing their tension to take place in two distinct movements. This hypothesis appears to me impossible to accept: such change would surely be likely to produce murmur rather than reduplication. But Guttmann says that reduplication of the second sound in mitral stenosis is difficult to account for satisfactorily, and in this I quite agree with him. He adds, "The broken diastolic sound is (so far as I have observed) certainly not loudest over the large vessels, but at the lower part of the sternum and near the apex of the heart, and is further absent in the more marked cases of mitral contraction, precisely in the cases in which the conditions most favorable to the postponement of the closure of the pulmonary valve are present in their highest degree." Reduplication, however, does not occur in mitral regurgitation, where the conditions of relative blood pressure are profoundly altered. Guttmann considers it probable that the reduplication may arise at the narrowed mitral orifice itself, that it may be a component part of a presystolic (or, as he terms it, diastolic) murmur, and adds that it has been conjectured that the first element of the reduplication is the diastolic pulmonary sound, and the second is produced, toward the end of diastole, by the contraction of the hypertrophied left auricle. In fact, the hypothesis reverts to the last I have mentioned as probably explaining some cases of reduplication of the first sound.

I consider, then, that there is a theory of auricular causation of reduplication of the second sound which is well worth considering, and that we have before us as plausible explanations of the phenomenon—

(*a*) That it is due to non-simultaneous closure of the semilunar valves in the aorta and the pulmonary artery respectively.

(*b*) That it is the effect of a sudden tension of the mitral curtains after the normal second sound.

Investigations into the Alleged Germ Origin of Malarial Fevers.

It is well known to our readers that various observers have claimed to have discovered the minute organisms which give rise to malarial fevers. Chief among these of late have been Klebs, and Tommasi-Crudeli. Their experiments have been closely followed, and an independent series of investigations made by Dr. George Sternberg, surgeon U. S. A., while at New Orleans. His report is in Supplement No. 14 to the *National Board of Health Bulletin*, accompanied by photographs and charts, and his results are so interesting that we quote his conclusions in detail:—

A great number of minute algæ, including bacteria of various forms, are found upon the surface of swamp-mud in the vicinity of New Orleans, and also in the gutters within the city limits.

Many of those forms may be successfully cultivated in fish gelatine solution (method of Klebs), and this fluid, previously innocuous, acquires pathogenic properties as the result of inoculation with these organisms.

It is evident that the pathogenic properties acquired by gelatine solution and other organic liquids, after inoculation with bacterial organisms, is due, directly, or indirectly, to the presence of these bacteria, for, if they are excluded, such fluids may be kept indefinitely without undergoing change, and are innocuous when injected beneath the skin of a rabbit.

Some of the organisms found in swamp-mud, in gutter-water, and in human saliva are capable of multiplying within the body of a living rabbit, and the fluids and organs containing them (blood, serum from cellular tissue, spleen, etc.), possess virulent properties. In other words, an infectious disease is produced which may be transmitted from animal to animal by inoculation.

Among the organisms found upon the surface of swamp mud, near New Orleans, and in the gutters within the city limits, are some which closely resemble and, perhaps, are identical with the *Bacillus malariæ* of Klebs and Tommasi-Crudeli; but there is no satisfactory evidence that these, or any other of the bacterial organisms, found in such situations, when injected beneath the skin of a rabbit, give rise to a malarial fever corresponding with the ordinary paludal fevers to which man is subject.

The evidence upon which Klebs and Tommasi-Crudeli have based their claim of the discovery of a *Bacillus malariæ* cannot be accepted as sufficient; (*a*) because in their experiments and in my own the temperature curve in the rabbits operated upon has in no case exhibited a marked and distinctive paroxysmal character; (*b*) be-

cause healthy rabbits sometimes exhibit diurnal variations of temperature (resulting apparently from changes in the external temperature), as marked as those shown in their charts; (*c*) because changes in the spleen such as they describe are not evidence of death from malarial fever, inasmuch as similar changes occur in the spleens of rabbits dead from septicæmia produced by the subcutaneous injection of human saliva; (*d*) because the presence of dark-colored pigment in the spleen cannot be taken as evidence of death from malarial fever, inasmuch as this is frequently found in the spleen of septicæmic rabbits.

While, however, the evidence upon which Klebs and Tommasi-Crudeli have based their claim to a discovery is not satisfactory, and their conclusions are shown not to be well founded, there is nothing in my researches to indicate that the so-called *Bacillus malariæ*, or some other of the minute organisms associated with it, is not the active agent in the causation of malarial fevers in man. On the other hand, there are many circumstances in favor of the hypothesis that the etiology of these fevers is connected, directly or indirectly, with the presence of these organisms or their germs in the air and water of malarial localities.

The truth or falsity of this hypothesis can only be settled by extended experimental investigations, and while further experiments upon animals may lead to more definite results, it seems probable that the *experimentum crucis* must be made upon man himself.

In a disease not of a fatal character, and one for which we have a prompt and reliable remedy, it would seem that subjects for experiment might be found, especially among medical men and medical students, who have always shown themselves ready to subject themselves to inconvenience. or even to danger, in the pursuit of scientific discoveries of value to mankind.

The method of conducting such experiments which seems to me to promise the best results is the isolation and cultivation of the various organisms found in malarial localities, which may possibly be concerned in the production of malaria, a careful study of the life histories of these organisms, and an experimental investigation of the physiological action of each when taken into the stomach, or respired in a dry state, by healthy individuals. Such a study, to be of value, will necessarily involve a considerable expenditure of time and money, and requires that the experimenters shall be familiar with the most approved methods of making culture experiments, and with the technique of microscopical manipulations with high powers, improved illuminating apparatus, etc.

Another method worthy of trial in connection with this, would be to carefully study the bacterial organisms found in the mouth and alimentary canal of persons suffering from malarial fevers as compared with the common forms constantly found in the same situations in healthy individuals, with reference to the determination of the presence of unusual forms, or of an abnormal abundance of common forms, or of possible physiological varieties of these forms not possessing morphological peculiarities.

Finally, I may say that I entered upon this investigation without prejudice, but hoping that I might be able to confirm the conclusions of Klebs and Tommasi-Crudeli, whose researches were evidently prompted by a truly scientific spirit, and were conducted in accordance with strictly scientific methods. I believe that their work will prove useful in many ways to future explorers in this field, and have an abiding faith that light will eventually be shed upon this and similar problems by the persistent and intelligent application of the experimental method supported by all the resources of modern science.

Pink Eye in Horses.

Dr. C. E Page writes to the editor of the Boston *Medical and Surgical Journal* as follows:—

This disease in horses is one of the varieties of catarrhal or influenza colds, so called, prevalent in this climate among human beings, and springs from the same cause, namely, excessive, over frequent, or otherwise injudicious eating. The custom of working or exercising horses directly after eating; of feeding them directly after hard work, and before they are thoroughly rested; baiting at noon, when both these violations of a natural law are committed; these are the predisposing causes of pink eye, and of most diseases that afflict our horses. The symptoms denominated pink eye are not indicative of dangerous disease, unless feeding is kept up; but if it is, then pneumonia, which is merely an aggravation of the original disease, is very likely to result. Keep the horse quiet, dry, warm, and in a pure atmosphere. The nearer out-door air the better, and *stop his feed entirely* at the first symptom of disease, and he will speedily recover. As prevention is better than cure, horsemen will do well to heed the hint here given and keep their creatures from contracting this or any other ailment. It has been demonstrated in tens of thousands of cases, in family life, that *two meals* are not only ample for the hardest and most exhausting labors, physical or mental, but altogether best. The same thing has been fully proved in hundreds of instances with horses, and has never in a single instance failed, after a fair trial, to work the best results.

An hour's rest at noon is vastly more restoring to a tired animal, whether horse or man, than a meal of any sort, although the latter may prove more *stimulating*. The morning meal given, if possible, early enough for partial stomach digestion before the muscular and nervous systems are called into active play; the night meal offered long enough after work to ensure a rested condition of the body; a diet liberal enough but *never excessive*; this is the law and gospel of hygienic diet for either man or beast. If it be objected that these conditions cannot always be fully met in this active, work-a-day world, I reply, let us meet them as nearly as possible. We can, of course, do no more than this; but we can come nearer the mark on the two meal system than on three. I will add, *in parenthesis*, that the nervous disorder commonly known as "pulling" will yield readily to this principle of treatment. It makes the puller healthy; he is better nourished and therefore less "nervous"; and he will

do more roading, and without excitement or profuse sweating. He is not made less ambitious by reason of reduced muscular power, but by reason of better digestion and assimilation—more *nourishment* and less *stimulation*. Horse dealers, or others, whose business or pleasure depends on the plump appearance of their animals, regardless of the size of their muscles, who must have a horse fat if he is not fleshy, for style, may have to take the chances and feed three times a day; but of this I am by no means sure. I have never tried to fatten my horses, for I long ago learned that fat is disease; but I have always found that if a horse does solid work enough he will be fairly plump if he has two sufficient meals. Muscle is the product of work and food; fat may be laid on by food alone. But for perfect health and immunity from disease, restriction of exercise must be met by restriction in diet. Horses require more food in cold than in warm weather, if performing the same labor. In case of a warm spell in winter I reduce their feed, more or less, according to circumstances, as surely as I do the amount of fuel consumed. I also adopt the same principle in my own diet. The result is, that neither my animals nor myself are ever for one moment sick.

Eucalyptus Globulus in Typhoid Fever.

Dr. Benjamin Bell, F.R.C.S.E., writes to the Edinburgh *Medical Journal*, August, 1881:—

This short note is supplementary to a former one published in this Journal (vol. xxiii, p. 680). After mentioning in that paper the remarkable benefit which, in my experience, had attended the administration of the tincture of the *Eucalyptus globulus*, or blue gum, in certain cases of what appeared to be very formidable disease of the stomach, I suggested that the same remedy might be found advantageous in cases of typhoid fever. My grounds for forming this anticipation are obvious enough. The drug possesses *antiseptic* qualities; it acts, as we have seen, beneficially upon the lining membrane of the stomach, perhaps of the duodenum. The characteristic lesion to be chiefly dreaded in typhoid fever is an irritated condition, a congestion, an inflammation, passing into ulcers or sloughs of the small follicular glands of the intestinal canal.

Ever since venturing to make the suggestion referred to, I have kept it in view, prescribing a teaspoonful of the tincture of *eucalyptus*, well diluted, at regular intervals of three or four hours, in all the cases of typhoid fever which have occurred. My distinct impression is that, as a rule, the duration of the disease has been shortened, and the tendency to diarrhœa diminished. If mixed with a large wineglassful of water, the medicine is far from disagreeable to the patient, and may be steadily administered in the intervals of nourishment without becoming irksome. By food, I mean milk and lime-water. As each dose of the tincture contains a drachm of spirits of wine, it is worthy of consideration that we are, in fact, giving a slight stimulant, not only well diluted, but possessed of a medicative property at the same time. This may, therefore, come in lieu of those other stimulants so often deemed desirable, at least in the advanced stages of the fever, while, in the intervals of the bland, milky nutriment, it will be brought into immediate contact, as an antiseptic, with the seat of threatened ulceration and sloughing.

In private practice, with a comparatively small number of cases, it would be rash to speak dogmatically as to the results of treatment; but a reliable opinion might be arrived at, were physicians connected with a large hospital which admits fever cases to employ the remedy in every *alternate* case under their care. If those patients who got the medicine were found—after its employment in a considerable number of cases—to have made more rapid recoveries with fewer bad symptoms than those from whom it was withheld, it would be reasonable and safe to draw an inference in its favor.

I may mention that my confidence in the *eucalyptus* in cases such as those formerly described continues unabated. Indeed, it has been strengthened, not only by the results in cases coming under my own observation, but also by several aggravated examples throughout the country, reported to me by the first patient to whom I administered it. He had benevolently recommended it, on his own responsibility, when he heard of persons suffering similarly to himself, before his restoration to health.

Paralysis Simulating Plumbic Wrist Drop.

The St. Louis *Medical and Surgical Journal*, for September, 1881, contains the following report of a somewhat interesting case, by Dr. C. H. Hughes of St. Louis:—

Sadie F., married, aged twenty years, came under treatment October 23d, 1879, with persistent inability to extend the hands at the wrists, both of which dropped lifeless, like those of painter's palsy. When the hands hang at her side she feels as though they were full of blood. Some years ago this lady had rheumatism, of which there are, however, no remains. In June, of 1879, she had some kind of symptoms of a form the exact nature of which could not be distinctly made out from her description, during which she was frequently delirious. I infer, however, that it was typhoid with tardy convalescence and *cachœmia*. Several irregular physicians attended her; among them a locally famous faith doctor (called, on account of his negligent *personnel*, the dirty doctor) who, though interrogated about the patient on an occasion when he had summoned me to examine and advise concerning his insane wife, could give me no information of value. About August 1st, 1879, this person found she could not move at all; but she grew gradually able to move all parts of her body, except her wrists. When first able to move about, after her fever, she weighed 77 pounds, and two months later she weighed 110 pounds. During her illness she lost much sleep and ate little, but at the beginning of this report, she ate and slept well. Her general tactile sensibility was normal, even in the fingers of the affected hand, and she told me she had always had some feeling in them. Electro-muscular excitability in the parts remaining paralyzed was, in the beginning of treatment, extinct. The temperature of the

right wrist was 98° F., that of the left, 99° F. Under the daily use of galvanism, arsenic, phosphorus, and at night only the least depressing of the bromides, with malt and a generous diet, the paralyzed parts entirely regained, in a few months, their normal power of movement, and the patient, though of small stature, soon reached her natural weight of 130 pounds; no strychnia was employed. Duchenne's observation respecting the more favorable progress of traumatic paralysis, where muscular sensibility remains after the loss of contractility under the electric current, finds confirmation in this case.

The case is noted to show the fact, not infrequent in paralysis of the extremities, viz: That notwithstanding a paralyzed limb has remained long *in statu quo*, galvanism combined with proper internal therapeutics may excite anew the arrested progress towards recovery, and that a hope of escape often remains to the hopeful and persevering.

Addison's Disease.

At a meeting of the Pathological Society of London, held Tuesday, December 20th, 1881, reported in the London *Lancet*—

Dr. Fenwick showed a specimen of Addison's Disease of the supra-renal capsules, from a case without bronzing of the skin. The man was recently in the London Hospital, under the care of Dr. S. Fenwick. He was a laborer who had had fair health. About four months previously he caught cold: a month afterwards his urine became high-colored and scalding, and he was languid and suffered from vomiting. On admission he was very languid; the pulse was very feeble; there was no pigmentation of skin or the mucous membranes, and no signs of visceral disease; there was tenderness over the epigastrium. Addison's disease was diagnosed. On September 28th, on attempting to get out of bed, he fainted, and soon after died. At the autopsy the organs generally were healthy. The liver was enlarged, and the left kidney was much larger than the right. Both supra-renal capsules were enlarged, hard, and nodulated; they were translucent, and in places yellow. He had collected all the cases of Addison's disease recorded in the Pathological Transactions during the last fifteen years, and found they were thirty in all, twenty-three males and seven females. The youngest age of females at death was five, the oldest fifty-five; the youngest age of females nineteen, and the oldest fifty-five. Average duration of illness in non-bronzed cases was 4.8 months, but in bronzed cases it was 26.8 months. If patients, without bronzing of the skin, died in one-fifth of the time of the others, the greater fatality was due to the constitutional disease, and the mischief causing this must be more intense. The two non-identical effects must have two different causes, or the same cause acting upon two different parts; the former idea might be certainly excluded. He thought the constitutional changes were due to degeneration of the medullary part of the supra-renal capsule, while the pigmentation was due to a chemical change in the blood resulting from the degeneration of the cortex of the capsule. The skin was well bronzed in nineteen cases, slightly or not at all in eleven. In four out of these eleven cases only one capsule was affected, and more often the right. In the case shown to-night the disease clearly mapped out the medulla. Dr. Wilks said that Addison had known that in the early stage the bronzing was less marked, and thought that some cases died before bronzing occurred.

Smallpox, followed by Ataxy.

At a meeting of the Harveian Society of London, held November 17th, 1881, and reported in the London *Lancet*—

Dr. G. C. Henderson read the report of a case of smallpox followed by ataxy. The patient, G. A., aged thirty-six, was admitted to the St. Pancras Tent Hospital, on May 29th, 1881. His temperature, which had ranged from 100° and 102° F., rose suddenly, on May 31st, reaching in a few hours 107.8°, and he was then immersed in a bath at a temperature of 68° for fifteen minutes. His temperature was then 96°, but it rose gradually in the course of the next eighteen hours to 104.4°. The bath was repeated. No hyperpyrexia or other complication followed, but convalescence was much protracted, large bullæ having formed on the soles of both feet, leaving scales, which separated very slowly. On July 18th, when he began to get up, he suffered from numbness and tingling of the feet, legs, and hands; the knee jerk and ankle clonus, as well as the skin reflexes, were absent; and he lost his balance when his eyes were closed. After leaving the Tent Hospital he attended as an out patient at University College Hospital. He slowly gained power in his legs, but when last seen the knee-jerk was still absent. Dr. Henderson referred to similar cases recorded by others, and considered the lesions causing the patient's symptoms were probably analogous to those found in diphtheritic palsy, and other forms of paralysis noted after acute diseases. They differed from those of true locomotor ataxy in the more favorable course which they took, ending in the majority of cases in recovery. Dr. Whipham had had two cases similar to Dr. Henderson's. Neither of them was treated with the cold bath, so the suggestion that the ataxy had had anything to do with the cold bathing might be dismissed. Both patients talked in a peculiar manner. Another point to be noticed was the irritability of temper which he thought most of these patients suffered from. Dr. Broadbent thought Dr. Henderson's notion as to the origin of the paralysis was the correct one.

A Penetrating Pistol Wound of the Brain.

Dr. J. Foster Bush reports the following case in the Boston *Medical and Surgical Journal*:—

A stout German, sixteen years old, was, on June 29th, while playing with a younger companion, shot in the head, and immediately fell to the ground insensible. I saw him within ten minutes after receipt of the injury. He was lying upon a sofa, breathing heavily, with a slow pulse, the mouth drawn to the left and the left arm and

leg paralyzed. It was with difficulty that he could be roused.

Upon examination a small round wound, with inverted edges, was found in the forehead, over the centre of the right eye and an inch above the eyebrow. Blood was oozing from the wound. Without the use of force, simply by its own weight, a probe passed into the wound penetrated backward to the depth of two inches. The opening in the skin was then enlarged so as to admit the tip of the little finger, and with this a circular hole could be felt in the skull. The patient was put to bed, cloths wet in ice water applied to the head, and the wound dressed with a two and a half per cent. solution of carbolic acid.

Two hours after the receipt of the injury he became perfectly unconscious, and could not be roused. Both pupils were dilated, the right fixed, the left responding to light. Five hours after the injury his condition was about the same as when last seen, the only new symptom being vomiting. Cerebral substance in masses as large as a split pea were noticed coming away with the blood. Upon examining the opening in the skull with a probe, small particles of lead were removed. Absolute quiet and rest were enjoined; liquid diet in small quantities ordered; dry cold, in the form of an ice-cap, was applied in the place of the wet compresses; and a one per cent. solution of phenyle was used in place of the carbolic dressing.

The next day the right pupil was largely dilated and did not respond to light. He stated that he could not see out of his right eye. Ten grains of bromide of potassium were given every three hours.

On July 3d there was a sero-purulent discharge from the wound, the pulse was 100, the temperature was 102.4° F., and the pain in the head was increasing.

On July 8th sight in the right eye was perfect; the headache was slight and local. For the first time since the accident he felt hungry. There was hemiplegia, with loss of both motion and sensation, and the skin of this side was colder than the other. Upon tickling the sole of the left foot the right leg would be drawn up. He also experienced spasmodic pain from left hip to the heel, and was able to move the leg for the first time since the receipt of the injury.

From this time on he gained in strength constantly, relished his food, and if he kept quiet, felt nicely. It was forty-one days from the time of the accident before he could move his arm, and up to this time he could not sit up in bed without experiencing nausea, or feeling as if "something was rolling about in his head."

It is now seven months since the receipt of injury and the patient has perfect use of both the arm and the leg of the side which was affected. He can walk without any support, and has complete control of the muscles of the arm and hand.

Although the symptoms and progress have been favorable, and there are now no alarming circumstances, I do not feel that we can give a favorable prognosis, for although wounds in the anterior and upper portion of the hemispheres are least dangerous, yet the risk of continued cerebral symptoms, epilepsy, abscess of the brain, and death from acute cerebral disease are great.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Transactions of the State Medical Society of Wisconsin, for 1881. This volume contains much that is interesting; notably an address on the "Influence of Mind upon the Body," by the president, Ira Manley, M.D.

——The *Half-yearly Compendium of Medical Science*, edited by D. G. Brinton, M.D., Part XXIX, for January, 1882, has been issued. It is a complete and thorough condensation of the progress of the last six months in medical science.

——"Anæsthetics, Medico-legally Considered," is the title of an address delivered before the Medico-legal Society of New York, Dec. 7th, 1881, by J. G. Johnson, M.D., of Brooklyn, and comes to us in the form of a reprint from the Bulletin of the Society.

BOOK NOTICES.

A Treatise on Aural Surgery. By H. McNaughton Jones, M.D., F.R.C.S.I. and Edin., Surgeon Cork Ophthalmic and Aural Hospital, etc. Second edition, revised and enlarged. pp. 344. J. & A. Churchill, London. 1881.

The author of the book before us is so well known, not only in Great Britain and the continent, but also in the United States, that the second edition of his treatise on Aural Surgery comes with an established reputation for practical worth that commends the same to all interested in this special department. With a Sir William Wilde at the head of a list of Ireland's surgeons, the Emerald Isle has just reason to be proud of having done her full share towards the advancement of general and special surgery. Although Wilde's glorious work on the Ear is now over a quarter of a century old, it bears the full light of to-day's criticism, and Jones' work gives, in a concise and practical form, with his own, the most modern views on otology. The entire book is rearranged. The author has added several chapters, and fully maintained the essentially practical character of the work. Dr. Jones acknowledges many useful hints and suggestions from such authorities as Weber-Liel, of Berlin, and Löwenberg of Paris. A series of translations by the author, from Dr. Löwenberg's work on "Adenoid Tumors of the Naso-Pharynx," have been condensed and added, in the form of a special chapter. Dr. Morrell Mackenzie contributes additions to the portions of the

work bearing on the throat, in the chapters on rhinoscopy, enlarged tonsils, and post-nasal catarrh. Dr. L. Turnbull is quoted on tinnitus aurium, the education of the deaf mute, and the influence of sea-bathing in causing deafness. Dr. Ringrose Atkins has rewritten the chapter on othæmatomata. Throughout the entire work valuable practical hints are to be gained from the author's experience, derived from the examination and treatment of upward of 5000 aural patients. Twenty chapters are in turn introduced by a carefully arranged table of contents, and closed by an appendix wherein is considered several important therapeutic hints, a list of authorities quoted, and a first-class index.

Suppression of Urine. Clinical Descriptions and Analysis of Symptoms, by E. P. Fowler, M.D. New York: William Wood & Co. 1881.

This is a small book (only eighty three pages), that no progressive physician can afford to do without. Dr. Fowler commences by giving the report of one remarkable case of complete anuria (in which the suppression was absolute for ten days and two hours), occurring in his own practice, and in which a most interesting autopsy was added, to make clear a most remarkable series of symptoms. This case is followed by tables of ninety-three cases of anuria, collected from the medical literature of the last one hundred years, and these, in turn, are followed by statistics respecting anuria and associated symptoms. Diseases of the kidney are frightfully prevalent, and seem to be rapidly on the increase. Scarcely a day passes that we do not hear of some friend or some public man dying from kidney disease. Unfortunately, our knowledge of the therapeutics of renal diseases has not increased in the same proportion that our familiarity with their pathology has. Therefore, it behooves every physician to turn a good share of his attention in this direction. While this little book does not materially add anything to the therapeutics of anuria, yet by directing medical energy into that channel, it will be productive of good fruit.

Frozen Sections of a Child. By Thomas Dwight, M.D., Instructor in Topographical Anatomy and Histology in Harvard University, etc., with fifteen drawings from nature, by H. P. Quincy, M.D. New York: William Wood & Co., 1881.

This book possesses the merit of originality and well executed drawings. The drawings are life-size, and the sections were made from a child three years of age. The body was first frozen so hard that the operator was unable to tell whether he was sawing through muscle or bone. The sections were then made and preserved in cold alcohol. Dr. Dwight believes that this method of preparing specimens for anatomical teaching is destined to become universal. His work has been executed admirably, but the book is not calculated to be of much service to the busy general practitioner, while to the anatomist, or to one who desires to become familiar with everything that is new, it will prove very acceptable.

Lectures on Electricity (Dynamic and Franklinic) in its relations to Medicine and Surgery. By A. D. Rockwell, A.M., M.D., Electro-Therapeutist to the New York State Women's Hospital, etc. New York: William Wood & Co. 1881.

A series of lectures originally published in a medical journal, and now brought together in book form. It is really a supplementary brochure to the larger work on electricity by Beard & Rockwell. This is the second edition, and contains some valuable improvements and additions to the first; prominently among them may be noted a description of the "galvanic accumulator" for storing electricity for surgical uses, and of the "induction balance," which was used in the case of President Garfield, to endeavor to locate the bullet, with what signal failure we are all well acquainted. To those who possess the larger treatise, this small book of one hundred and twenty pages will form a suitable companion.

A Study of the Tumors of the Bladder. By Alexander W. Stein, M.D., Surgeon to the Charity Hospital, etc. New York: William Wood & Co. 1881.

This is an interesting subject, about which comparatively little has been written. Dr. Stein had four interesting cases under his care, which caused him to take an interest in the subject, and, as a result, this monograph was written. It is in reality a compilation from the periodical literature of the day, well arranged and illustrated. He divides tumors of the bladder into benign and malignant growths. Among the former are included papillomata, myxomata, fibromata, and myomata. Under the latter, carcinomata, and sarcomata. He has collected and classified a very large number of cases, which tend to make this a valuable monograph.

A Treatise on Diseases of the Eye. By Henry D Noyes, A.M., M.D., Professor of Ophthalmology and Otology in Bellevue Hospital Medical College, etc., etc. New York: William Wood & Co., 1881.

This is the December number of Wood's Library, already so well known as to require merely an announcement.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,

115 South Seventh Street,

PHILADELPHIA, PA.

PREPARATION FOR MEDICAL STUDIES.

We have heretofore referred, in a somewhat too brief manner, to the new department in the University of Pennsylvania, which has been created with the special object of preparing young men for the study of medicine.

In the comments which have appeared in the medical press on this subject, it appears to us that the one most important feature of the case has been not fully enough dwelt upon. To lengthen the period of medical studies out to the European standard is, as yet, absolutely impossible. Yet our schools attempt to cover nearly the same ground that the foreign institutions do. The inevitable conclusion is, then, that when we attempt to crowd a full four years' course into two, or at most, three winters, we, by that very fact, institute a process of cramming which is bad for the individual student, and worse still for the prospective doctor, because it introduces him to and carries him through his period of preparation in the capacity of a mere receptive machine, allowing no, or next to no, time for proper culture of habits of observation, or his reasoning and comparing faculties. Bad as this is, it has probably been unavoidable. The new department of the University promises most effectually to obviate this. In fact, it is but a most rational extension of the idea expressed in the month of preliminary lectures which some of the leading medical colleges had already instituted. Practically it is adding another year to the medical course, by the manner in which it specifically fits the student for medicine, as it familiarizes him with technical terms, teaches him the use of implements of research, and opens the trails which broaden into well-trodden avenues to medical knowledge as he advances. While it affords opportunity to the regular student of a collegiate or scientific course to diverge from the ordinary curriculum, it also admits such special students as may have neither time, inclination nor means, to a special preparation, stipulating only that they shall have such preliminary general culture as would enable them to pass the examining board instituted by the county societies at the suggestion of the State Medical Society. Of these certainly the fuller course is the more desirable, on the general principle that one cannot have too much mental training, or too large a grasp of facts; but the second is a great advance on any plan hitherto devised for elevating the standard of the profession. The most cheering aspect of the move is that before the department is one session old it has shown such signs of vigor, and has been so well received, that its success is absolutely assured.

Taking the student through comparative to human anatomy; through physiological and analytical botany to study of the plants used as remedies; through general chemistry, so as to fairly ground him for medical chemistry; through physics far enough to enable him to apply laws of light, sound, etc., to the instruments he will use in after life; giving him also, if time allows, a good start in Latin, French and German, and also English literature; such a course cannot fail to fit an industrious lad for a high stand in his future profession, and one, too, which must tell

in his favor when he enters the crowded medical ranks, as a competitor for public patronage. It is to be remembered that this course is taken, not from text-books, but, so far as possible, by laboratory work, where all that is learned is apt to be retained; giving, beside, the largest stimulus to correct observation and correct judgment.

There are, so far as we can see, but two weak points in the whole plan: First, that elementary physiology has been omitted; and second, that no institution in the land is yet able to demand some such preparation before allowing students to matriculate in medicine proper. The first of these defects will doubtless be remedied during the year. The second is probably a question of longer time. But when law and theology both demand adequate preliminary tests for actual attainments and for mental training, it is hardly conceivable that our own profession will be content forever to bring up the rear. There is some comfort in the fact that Philadelphia has been the first to hit upon and to fairly grapple with a system of preliminary medical culture which promises such good results.

MILK DIET IN BRIGHT'S DISEASE.

Since we know not at present any drug that possesses therapeutic value to any marked extent in this terrible and fatal disease, and since it is daily making sad havoc among human beings, and principally among that class who, by reason of their valuable public labors, are particularly necessary to the welfare of the world; therefore, it becomes a medical question of paramount interest, that we should discover some potent method of combating this very prevalent disease. Some years since CAREL first called attention to the treatment of Bright's disease by the use of a milk diet, and since then DUNCAN, as well as many other prominent physicians, have written on this subject. We have ourselves seen some remarkable results follow this treatment, while Dr. S. WEIR MITCHELL, of our city, is now quite an enthusiast on this subject. This method of treating a formidable disease has received sufficient distinguished endorsement to recommend it seriously to our notice. We would, therefore, ask all physicians who read this article to try this method of treatment, and to furnish us with their experience, which we will publish. The milk is used thoroughly skimmed and entirely freed from butter. To procure the best results, it has been advised that the patient shall restrict himself absolutely to milk, and continue the treatment for a long time. If it disagrees with the stomach (as it will in some cases), Dr. MITCHELL advises that the patient be put to bed, and the treatment commenced with tablespoonful doses, to which lime water is added, until the stomach tolerates the milk, when from eight to ten pints daily should be taken, and absolutely nothing else. The sanction of such a distinguished physician as Dr. MITCHELL forces us to seriously consider the merits of this treatment, and we trust to receive the experience of all readers of this journal who may have cases of Bright's disease to treat.

NOTES AND COMMENTS.

Ephidrosis.

The above name has been given to a disease of an unknown nature, but characterized by profuse sweats, returning at variable intervals, usually, every year, at the same date. That distinguishes this morbid condition from the sweats attending intermittent fever, or the colliquative sweats in phthisis, or those in miliary fever. Ephidrosis is chiefly met with among sufferers from constitutional gout, among hypochondriacs, and in certain neurotic affections unattended by gout, but in which sudation seems to be the result of nervous perturbation. Several instances have been observed which may be likened to the following case described by Dr. Olivier, in 1881, in the *Arch. de Méd. Nav.* A non-commissioned officer was admitted to the Toulon hospital, having, for a month past, been suffering from profuse sweats. He had contracted intermittent fever in 1862, and since then was subject to such attacks every year. These copious sweats continued after the patient's admission; his garments and bed clothes being thoroughly saturated by the liquid thus abundantly secreted each day, from nine in the evening till midnight. The sweat was liquid, acid, then alkaline, and its temperature that of the body. The skin was turgescent, and congested,

but of normal temperature. The sweats were often preceded by a chill, and when they were over the patient slept, and only complained of fatigue. During his stay at the hospital some prurigo was noticed, also some erythematous and lichenous eruptions, attended with itching. Otherwise all the other functions were normal.

Mr. Olivier attributed this hyperhydrosis to a psychical cause. He classed it with Spring's phrenopathic variety, and believed it due to moral emotions, from which the patient often suffered. Country air, absence from care, and tonic medication, combined with hydrotherapy and antispasmodics, were found of greater benefit to the patient than all the remedies administered while under treatment at the hospital.

This case might also be considered as resulting from *larvated fever*.

Can a Threatened Attack of Diphtheria be Averted?

Dr. Alfred Sheen, Surgeon to the Cardiff Infirmary, writes to the editor of the London *Lancet* on this important subject. His question is based on this fact: He was called to see a young woman who had nursed her brother through a fatal case of diphtheria. Four days after his death she was seized with general malaise, shivering and thirst. Pulse, 144. Temp. 103.4°. She did not complain of her throat, which, on examination, presented a normal appearance. She was given twenty five grains of ipecacuanha powder at once, and one ♏ of the tincture of aconite every quarter of an hour, for the first hour, and every hour afterward. The next day her pulse was 94 and temp. 99.8°. On the next day her *throat was painful and congested*, but no patches. She was ordered:—

℞.	Liq. ferri perchlor.,	f℥ iv.	
	Potass. chlorate,	℥ ij.	
	Glycerinæ,	f℥ ij.	
	Aquæ,	f℥ vj.	M.

Sig.—f℥ ss every four hours, in water.

Two days afterward pulse was 76 and temp. 98°. Congestion gone and the girl said she was quite well. Dr. Sheen then asks: "Was this woman, when I first saw her, suffering merely from a sharp attack of febricula, brought on by fatigue, anxiety about her brother, and subsequent exposure at the funeral, or was she in the early stage of diphtheria?" He adds that, "As a rule, specific febrile diseases are not averted by treatment, but may that not be because we do not get hold of the disease early enough." (?) In view of the fatal nature of this disease, and the uncertainty surrounding its pathology and therapeutics (so great that a distinguished French lady has offered a reward of five thousand dollars to any one who may discover a preventive), this query is worthy of attention and investigation, and we will be glad to hear from our readers on the subject.

Phenic Acid; Its Antithermic and Apyretic Effects in Typhoid Fever.

Mr. Van Oye has lately finished an interesting thesis on the above subject, and these are his conclusions, as published by *Paris Médical*, *No.* 46:—

1. Phenic acid acts as a poison on the nervous system, and possesses, to a high degree, the faculty of reducing temperature, both in man and the higher animals.

2. Doses having no appreciable effect on the normal temperature are sufficient to reduce the febrile temperature.

3. This reduction takes place in all fevers, whether simple phlegmasias or infectious pyrexias.

4. Its effects appear a few moments after the medicine has been taken; their range is from 1° to 3° Centigrade, according to the dose given, and they continue from one to three hours.

5. Its action is probably due to the loss of caloric resulting from cutaneous hyperæmia, and the more or less abundant sweats coinciding with its production.

6. When the antipyretic effects of a dose are exhausted, a chill supervenes, all the febrile phenomena return, and the temperature suddenly rises to, or even beyond, its former degree.

7. A fresh dose will counteract this paroxysm, or prevent its return, if administered in time.

8. Doses that are sufficient to produce all the required antipyretic effects do not exercise any immediate noxious or toxic action on the patient.

9. Fifty centigrams (gr. viiss) administered *per rectum*, are in all cases sufficient at the outset. In general, the dose can be progressively increased until it reaches two grams *pro dosi* (℥ ss), and twelve grams *pro die* (℥ iij).

10. A dose of one gram (gr. xv) has, in some special cases, lowered the temperature down to 34.5°. This exaggerated reduction has, in no case, been attended with any evil results for the patient.

11. Pulmonary congestions are the danger to be feared and avoided.

12. Albuminuria, polyuria, and fatty degeneracies are the possible effects which may result from large and long continued doses.

13. The antipyretic properties of phenic acid

should be reserved to be used against hyperthermia in continuous fevers, or paroxysms in intermittent fevers.

Cliterodectomy.

Dr. George J. Engelmann contributes a very valuable and interesting paper on this subject, to the *American Practitioner* for January. He thinks the operation has fallen into undeserved disrepute, and advocates its performance in certain cases. His justification for the operation is based upon a recognition of the importance of reflex action in female suffering. He gives a complete record of one case (the only one he has ever seen), in which a lady, fifty-two years of age, was placed under his care for the following condition: She had always suffered much from headache, and was very nervous, easily flushed by worry or excitement. She has had eleven children; menstruation had always been regular, but profuse, until about six years ago, when, after eighteen months of irregularity, it ceased altogether. She complains of nervous attacks, originating sensibly in the region of the clitoris, and culminating in melancholia. All the symptoms of the attack evidence a profoundly nervous condition, and great derangement of the general health. After lasting a variable period, these symptoms would suddenly disappear, and she would have two or three weeks of comparative comfort, followed by a fresh attack, until life became a burden. Examination revealed an irritated vulva, carunculæ myrtiformes, and very much enlarged nymphæ and clitoris. He removed the carunculæ, and subsequently amputated the clitoris and nymphæ. The patient made a good recovery, and while under his care was entirely free from bad symptoms. Some months afterward, however, when she had returned home, the old attacks came back with full force, but Dr. Englemann attributes this relapse to a return to her old habit of masturbation, which, of course, the presence of the nurse had prevented. The question therefore arises, whether her nervous attacks were due to the enlarged clitoris or to masturbation. This opens up a wide field for investigation.

Forced Feeding in Phthisis.

From the London *Lancet* we note, M. Debove has lately urged the importance of the forcible feeding of phthisical patients by means of the œsophageal tube, and his favorable results have been confirmed by M. Dujardin Beaumetz. In some cases the stomach is first washed out, and then food is introduced, easily digestible—milk, eggs, pounded meat, etc. Patients are said rapidly to regain appetite, strength, and nutrition, and to lose their pyrexia, night-sweats, and vomiting. The tolerance of the stomach for food thus introduced, even in considerable quantity, is said to be remarkable, and even the most troublesome cough no longer causes vomiting. M. Dujardin-Beaumetz has employed for this purpose an œsophageal tube, one-third of an inch in diameter, and gives by it about three and one-third ounces of raw meat, four eggs, and about two quarts of milk at a time, and four and a half to six fluidounces of cod-liver oil. He prefers to feed the patient in this manner twice in the day, and has also observed under this treatment an improvement in the pulse, a diminution in the fever and in the sweating, but he has not yet observed a decrease in the pulmonary disease.

Excision of the Pylorus.

At the meeting of the Royal Medical Society of Vienna, on December 16th, Dr. Wölfler exhibited a woman upon whom Professor Billroth had performed resection of cancerous pylorus two months before. The procedure in that case differed from that of others in that the duodenum was not at once divided, but its posterior wall was first fixed to the stomach by sutures. The operation lasted an hour and a half. Microscopic examination showed that glandular cancer existed, but that no cancer elements had yet appeared in the lymphatic glands extirpated at the same time. Dr. Wölfler also showed the woman upon whom he had similarly operated eight months before. No recurrence had taken place. Her digestion is quite normal.

In view of our present powerlessness to medically treat cancer of the stomach, every successful case of surgical interference seems like a beacon giving evidence of the halcyon days ahead, when we may reasonably hope to afford relief from this terrible disease.

Akido-galvano-cautery for Epilation.

Dr. C. Heitzmann, of New York, read a paper on this subject before the American Dermatological Association, at Newport, in August last, which has been published in the January number of the St. Louis *Courier of Medicine*.

After discussing the failure of the means hitherto recommended, he comes to the con-

sideration of electrolysis, which term he does not like, since it would convey the idea of an electric action on the tissues, without thermic influence. What we use for the destruction of hairs is the galvanic current, and, as it seems, its thermic action, therefore galvano-cautery. The action being induced by a delicate needle, the work *akis* could be attached, and *akido-galvano-cautery* or *akido-cautery* would be a more correct term than *electrolysis*. The battery he used consisted of sixteen cells. At first the action of the galvanic current was very slow, due to an insufficient moistening of the sponge, which the patient held in her hand. If the sponge was kept well soaked in water, six or even five cells were sufficient to render the operation successful and almost painless.

The needle attached to the negative pole was inserted into the hair pouch, without touching the hair itself, so that the negative pole was applied to the bottom of the hair pouch, the positive, by the sponge, to the hand. A whitish discoloration around the needle, detached epidermis, a little frothing, and subsequently, a marked redness around the needle, occurred. The loosened hair was then removed (without any force) by tweezers; the root was slightly discolored, and looked as if burned through. A second insertion of the needle into the gaping pouch is advisable. A small papule or pustule follows the operation, which will heal up without leaving any scar worthy of note. Failures will occasionally occur, but Dr. Heitzmann operated upon four hundred and fifty hairs and six months afterwards only six hairs had recurred, which readily yielded to a short operation.

Inflammation of the Hair Follicles of the Nose.

The St. Louis *Courier of Med.*, says: Dr. Hardaway called the attention of the St. Louis Medico-Chirurgical Society to the inflammation of the follicles of the small hairs in the nose. They give intense pain, and there is much inflammation externally as well as within, and very frequently, after the inflammation of the hair follicles subsides, it is followed by *exfoliation* of the outer portion of the skin of the nose; in other words, the patient has a very red nose. Externally, it is generally limited to one or the other side; there is a great deal of sharp, very acute, intense pain. The cases generally continue for weeks, very frequently last several weeks, and when it subsides, there is considerable epidermic shedding—desquamation—showing the violence of the inflammation. They are cases that try the patience of the doctor and the patient both. Within the last year he has been using a treatment which has given great satisfaction. He uses Squibb's glycerole of the subacetate of lead and glycerine, one part of the first to seven of the latter. Under this treatment, the trouble disappears rapidly.

Successful Skin Grafting.

The *Paris Médical*, November 19th, 1881, reports the case of a man, thirty-seven years old, who for over six years had suffered from a varicose ulcer on the left leg. Every form of treatment had been resorted to without benefit. While in the hospital he begged of Dr. de Lamallerée to make one more effort in his behalf. The idea of skin grafting then suggested itself to the physician. The ulcer was 14 centimeters by 8. On this six grafts were applied, taken from skin off the abdomen of a young live rabbit, the hair having first been shaved off. Besides these, two other grafts of skin from the patient's forearm were also applied, and the parts were dressed antiseptically.

After eight days the dressing was removed, and it was found that the six animal grafts had fully taken; they were surrounded by healthy granulations; but the human grafts had not been successful. The dressing having been continued another eight days, inspection showed that the grafts formed a patch of healthy skin in the centre of the ulcer, 10 by 7 centimeters. After another week of antiseptic dressing, cicatrization was complete, and when the patient was again seen, two months later, he was entirely cured, and no rabbit hair had grown on the new skin.

Hypodermic Injection of Quinine.

J. B. Scriven, late civil surgeon of Lahore, writes to the London *Lancet* on this subject, and from his communication we note the following conclusions. There is no danger of abscess if proper precautions are used. He is always careful to introduce the nozzle of the syringe so that the aperture by which the quinine enters the cellular tissue shall be turned away from the skin. The result has been that he has never had a case of abscess, ulceration, sloughing, or evil effect of any kind, save a temporary inflammation of the arm requiring rest and cold lotions. It is well, from the moment of the injection, to give the limb absolute rest for a few days. He prefers the tartaric solution to the aqueous solution of the neutral sulphate, on account of its higher concentration. If the solution is free from visi-

bly insoluble particles, filtering is not resorted to. This is a valuable experience, inasmuch as the physician is apt to meet cases (particularly in puerperal fever patients) where, owing to uncontrollable vomiting and purging, this valuable drug can only be used hypodermically.

Case of Epilepsy Produced by Reflex Irritation.

The following is from the St. Louis *Courier of Medicine:* W. S., a boy aged eleven years, had been suffering from epileptic attacks for several years, which came on at different periods. The boy was rather emaciated, and of very nervous temperament. On examining the boy's penis, I found that he had phimosis, with a very small preputial opening. He told me that sometimes, when urinating, the prepuce swelled up by the urine which collected, and could not empty as fast as it came from the urethra, causing him some pain, which, however, he never told his parents. I then advised the parents to have the boy circumcised, which would materially help, if not entirely cure, this terrible disease of their son. They consented. The next day I performed the operation, having the patient under the influence of chloroform. The wound healed without trouble. From that day his nervousness grew less and less; he has had no other attacks; to-day, one year and a half after the operation, he is stout and fleshy.

Alcoholic Intoxication.

The London *Lancet* says that Lallemand, Perrin, and Duroy, have found notable quantities of alcohol in the blood of intoxicated animals. M. Grehant, in continuing these experiments, has endeavored to ascertain what proportion of alcohol in the blood is sufficient to produce and maintain symptoms of intoxication. Seven ounces of alcohol (21° strength) were given to a dog, in two doses, at an interval of half an hour. At the same time the animal was made to breathe through a flask containing absolute alcohol, to offset the influence of pulmonary exhalation. At the end of an hour, about two and a quarter ounces of blood were drawn from the femoral artery. It was found to contain about eight minims of absolute alcohol, which corresponds to one part of alcohol to 197 of blood. The animal was profoundly intoxicated.

Calabar Bean.

Every now and then an article appears in some journal about Calabar bean, and it is recommended for various diseases, notably in tetanus and epilepsy. The assistant editor of this journal wrote his graduation essay on Calabar bean, and in studying the literature of the subject, found so many cures of epilepsy reported that he was led to believe that we had almost a specific for this terrible disease. Subsequently, during an experience in a large hospital, he was afforded the desired opportunity of using the bean in a *very* large number of cases of epilepsy, and found it to be utterly worthless. It had no effect whatever, unless it may have intensified the paroxysms, since it was noticed in more than one case that a seizure for which the bean was given was more violent and lasted longer than another attack in the same person when it was not used.

Prevention of Hay Fever.

Mr. J. B. Hannay, of Cove Castle, Loch Long, N. B., writes to *Nature* that he has succeeded in finding a means for the prevention of hay fever. One thing which misled him was, that his eyes were often very much inflamed and pained during an attack, and he often tried remedies for his eyes when they were only affected in sympathy with his nose. He found that the only thing required was to prevent the entrance of the pollen grains into the nose. For this purpose he uses a piece of brass or steel ribbon, bent double, and having only sufficient spring to close the nostrils without undue pressure. When going among hay a further precaution should be taken, viz., plugging the lachrymal ducts. He used for this purpose dumbbell-shaped pieces of glass, which were easily slipped into the ducts, and could be removed when wanted.

Special Reports.

No. II.—ON THE EXAMINATION OF DEAD BODIES IN SUPPOSED CRIMINAL CASES.

BY GEO. F. SOUWERS, M.D.

(*Concluded from page* 81.)

In examining the body, the first points to be noticed are the approximate height, weight, and general physical condition of the subject; care should be exercised in this latter respect, from the fact that a defence might turn on the physical state of the individual, as in cases where it is charged that the deceased was maltreated or starved to death. Before touching the body, note should be made of the exact locality, position and attitude of the corpse; the situation it occupies relative to other articles (such as pieces of furniture) in the room; or, if found on the highway, or in the fields, the distance and direction from certain well-defined objects or near-by landmarks. Supposing these suggestions to have been observed, we will proceed to the next step, and this should be the observation of the degree of rigor mortis present; whether the limbs can

readily be flexed and extended, or whether they resist attempts at motion; it should be remembered that a limb in a state of rigor mortis can more readily be extended if it be first flexed or moved in the direction in which it normally acted during life. While ascertaining the condition we have just spoken of, the temperature of the body should be noticed, as this may throw some light on the length of time that has elapsed since the cessation of life, a question that might come up for discussion, where two persons being found dead at once, the heirs of either are to succeed to the whole of an estate upon the death of one, as where a will has been made, that if A die before B, the estate shall descend to A's heirs; but if B die before A, then to those of B, as in the case of a husband and wife having no children. Under these circumstances, if A's body were found to be entirely cold, whereas B's still retained its animal warmth (being of course exposed to the same circumstances and temperatures), the supposition naturally would be that A died first, and consequently, his heirs would be entitled to the inheritance. The next step in the examination is to ascertain the presence, number, seat, direction, depth and appearance of all wounds and scratches on the body, beginning from the hair and going down; any material found clenched in the fingers of the deceased should be retained by the examiner for future reference; this includes all such articles as hair, pieces of cloth, grasses, weeds, etc.; it may seem straining a point to suggest the retention of weeds, etc., but there are a number of instances on record where these, when submitted to the microscope, have proved that the deceased did not meet his death at the place in which the body was discovered. In case of lichens being found, it would be well for the physician, after finishing the principal examination, to seek to discover similar bodies in the locality in which the body is found, these to be used for purposes of comparison. In the observation of wounds, it is of primary importance that it be noticed whether the edges gape open and are everted, or whether the lips are more or less closely approximated; a wound that gapes must have been made before or very shortly after death, where the skin seems simply to have permitted the passage of a knife, or sharp instrument, without retracting from before it, it is good evidence that the wound was inflicted after and not before death, although, as Taylor remarks, a lateral motion given to the hand or the instrument in making a cut or stab, may be the cause of a certain amount of gaping. That wounds made before and after death should resemble each other more or less closely in respect to the degree of gaping present, it is necessary that they should have been made while the *animal heat* still remained in the body. Taylor, in some experiments on this point, made on amputated limbs, arrived at these conclusions in regard to the time at which retraction and the other symptoms of section during life ceased to appear. We place them in a tabulated form:—

Incision made two minutes after amputation, through skin etc., down to the deep seated fascia of the leg (calf).	Skin retracted so as to permit extrusion of adipose substance, on account of which protrusion there was but little blood effused, owing to mechanical pressure. The wound after 24 hours presented red, bloody and everted edges; skin not swollen, but slightly flaccid; coagula slight and at bottom of wound being readily broken up by the finger.
Ten minutes after amputation, similar incision on outer side of leg, down through the peronei and flexor longus pollicis.	Elasticity of skin lost; edges but very slightly everted; but little blood lost. In 24 hours afterwards the edges of the incision were pale and collapsed, presenting none of the characters of a wound inflicted during life; while there were a few coagula at the bottom of the wound, yet they were decidedly less in number than in the preceding instance.
Two to three hours after.	A little blood effused, but no coagula formed.
Twelve or fourteen hours after death.	No resemblance between wounds made during life and after the lapse of this period.
A wound with swollen and everted edges.	A wound inflicted before death.
A wound inflicted before death presents:	*A wound inflicted after death presents:*
1. Eversion of the edges, owing to the elasticity of the skin.	1. Edges not everted, but close.
2. Abundant hemorrhage, often of arterial character, with a general infiltration of the surrounding connective tissue.	2. Hemorrhage or bleeding exclusively venous; absence of copious hemorrhage, there being about the divided arteries no marks of blood, as

	there is where hemorrhage takes place during life.
3. The presence of coagula. (If there has been no bleeding of any account then these two latter signs may be wanting.)	3. No coagula and no infiltration of blood into the connective tissue.
4. The edges or lips of the wound are more or less resistant to pressure lightly applied.	4. Edges of the wound soft, yielding, and destitute of elasticity.

The above appearances should all be carefully noticed and note made at once of the appearance, location, measurements, condition, and direction of the wound or wounds; the exact time at which these observations are made should be noted, and if possible, comparison should be made with the time piece carried by the deceased; the need of this precaution may not seem clear to many, but we will explain. It is not an uncommon event to find a watch carried by a person who has met a violent death, especially where there has been a severe struggle, in which it has been subject to more or less rough usage, to be stopped; we have found that in ten minutes a dead body ceases to respond to certain tests to which a living body would, one of these being the retraction of the skin; now, if a person, being suspected of a criminal attack upon the deceased, attempted to prove an alibi, it would only be necessary, in the first place, for him to show where he was during the interim between the stoppage of deceased's watch and that of the physician; or, secondly, if. for purposes of experiment, a doctor, upon his arrival, made an incision upon the body, which incision gaped, consequently showing that only about ten minutes had elapsed since death, it would only be necessary for the prisoner to show his whereabouts during that or a shortly preceding time, instead of during seven, eight, or twenty four hours previous to the finding of the body, as is now frequently required.

A question here occurs which is of interest, namely, is it allowable to remove, or in any way interfere with the body of a person found dead? The common opinion seems to be that a corpse must not in any way be interfered with until the arrival of a coroner or his deputy: this idea, however, will admit of a modification to this extent: if a body be found hanging, it is allowable to cut it down; if drowned, to remove it from the water; or, if exposed, it may be taken to a place of shelter, providing always that the corpse be not taken from the neighborhood or locality in which it is found, to a distance. It would not be permissible to remove it from one section of the city or county to another, till the qualified officers of the law had issued a permit; nor would a doctor's certificate of death be issuable in such a case, unless first sanctioned by the coroner or his legal and proper representative, which sanction the physician should *demand in writing*, so that in case any question arose as to the authority by which he acted, he would be able to exhibit it; it may seem needless to take this precaution, but we have known of instances in which a neglect of it has caused very unhappy results for the practitioner. Where bodies are found under peculiar circumstances or conditions, care must be exercised lest too hasty conclusions are jumped at as to the cause of death; thus, a corpse being found near or on the banks of a stream, presenting the appearances of a drowned body, would seem, at first view, to be prima facia evidence as to the cause and manner of death, but it is just here that a mistake may occur; for instance: We are aware of two instances in which dead bodies being found on the margins of streams, it was supposed that the deceased met their deaths through drowning. Investigation disclosed the fact that the necks of both were broken. A question then came up, how did the accident happen? In both instances witnesses who were present at the time naturally concluded that the individuals had been drowned. On making examination of the places at which the deceased parties dove into the stream it was found that the water was shallow at these situations, and that a mistake had been made by the persons who had met their deaths, in judging of its depth, and that in consequence they sprang into the water head first, with such great force as to bring their heads in violent contact with the bottom; thus accounting for the production of the unfortunate sequelæ. We can readily see how, if these men had died, there being no witnesses present, and their bodies had been found in a deeper portion of the stream than that which they entered, with their necks broken, it might be debated whether they had come to their ends by fair or foul means, and a coroner's physician might well be asked if an accident such as we have spoken of could take place, on the trial of a person who might be suspected of being party to the death of an individual.

A physician being called to see a body found dead, or a person who shortly afterwards dies, should at once notify the coroner of the place in which death has taken place, and if there is no

such officer conveniently attainable, then those whose functions under the law come nearest to the powers usually lodged in that officer, namely, a Justice of the Peace, an Alderman, Burgher, or the chief officer of police in the district in which the event has happened. All effects of the deceased, any weapons or instruments of any kind found in the neighborhood of the corpse; all loose articles of clothing; or in cases of poisoning, all packages, bottles, samples of food, excretions, etc., should be retained by the physician until delivered by him to the proper officers of the law, to wit: the Coroner, Justice of the Peace, etc., above spoken of, in order that they may be used as evidence, if necessary, by the court, and that others may not remove them without authority. Of course, where a man dies suddenly, as from a heart disease, an apoplexy, etc., these precautions do not apply. We speak only of where there is good reason for the exercise by the physician of a reasonable degree of judgment, such as any sane and intelligent man is bound to observe, and which he, under the circumstances, as a physician, is supposed to be particularly qualified to employ. Where a post-mortem examination is made, not only the injured parts should be examined, but likewise all the organs of the body, so that it may be known whether there existed any diseased condition of the subject which, either of itself, or taken in conjunction with the injuries, would be likely to produce death. In other words, given a series of injuries to a man in whom certain organs are more or less diseased, would such a circumstance in any way tend to increase the chances of a person's death. This is an important point to be attended to, for the defence might argue that a man died of a diseased condition of some organ or structure, and not of the wound. The attempt being to prove, if not absolute innocence of the affair, then simply an assault and battery. This would make a strong defence, if a medical examiner had neglected to carefully inspect all the organs of the body, and his inability to testify, pro or con, in the matter would probably result, where his was the leading testimony, in exonerating the prisoner from the charge of murder.

Correspondence.

Smallpox Hospitals.

Ed. Med. and Surg. Reporter:—

Inasmuch as students and practitioners, as a rule, do not have access to smallpox hospitals, a study of cases in the wards may prove of service to them when called to decide on the diagnosis of *variola*. The classical divisions of the disease are discrete, confluent and hemorrhagic. All authors treat fairly of the first two forms, but the hemorrhagic is imperfectly described, if at all referred to. It should be divided into two classes. First, that in which, from a purpuric state of the blood hemorrhage takes place into the fully formed vesicle; and second, that in which there is a hyperæmic state of the papule from the outset. This latter class is nearly always confluent, and usually fatal. It is difficult to describe these papules more definitely than to say that they are broad, but slightly elevated, and nearly identical in appearance with the eruption of malignant measles. These papules do not fill as the ordinary ones do, but remain low and diffuse. The skin between the papules has a diffuse redness. The symptoms of this group of hemorrhagic cases are also peculiar; many begin with little or no fever, and up to the time of the appearance of the eruption, there is nothing to indicate the grave condition of the patient.

To illustrate the importance of a diagnosis and the difficulty of making it, the following case may be of interest:—

A gentleman connected with one of the daily journals called on his physician, stating that he was unwell, but not in a degree to cause any apprehension. He was requested to remain in the house for a few days. After a day or two, a rash appeared, and was considered to be measles. The rash, instead of becoming less pronounced, in a few days increased, and then the diagnosis of smallpox was made. The patient when removed to the hospital was able to walk to the carriage. He died on the fifth day of hospital residence.

As has been previously suggested, this class of cases is liable to play great havoc with the reputation of the physician by mistake in diagnosis and prognosis.

Delirium in any case of smallpox after the eruption has appeared, coming on at night, is not a serious symptom; but if it lasts twenty-four or forty eight hours, the chances of recovery are small. Convulsions are rare, but they do occur.

The eruption in smallpox usually appears on the third or fourth day, and the umbilication of the vesicles, though quite common, is by no means pathognomonic. It often happens that the eruption appears on the conjunctiva, and when it does so, it is on the palpebral surface. It is to be distinguished from keratitis, which is of frequent occurrence. The fever of suppuration takes place about the ninth or tenth day, and in fatal cases, where the patient does not die within the first few days, death occurs about the twelfth of the eruption, from asthenia.

Prognosis.—The mortality, including children and adults, is about twenty per cent. With children alone the rate is higher. In closely analyzing the varieties, we find that adults with the discrete eruption usually recover, even if, from a purpuric state of the system, blood has been effused into the vesicles. It will be remembered that these cases were classed as one of the classes of the hemorrhagic. When the disease is confluent, or seems confluent, there is an increase of the danger; and in the malignant form

referred to as the secondary division of the hemorrhagic, the prognosis is uniformly bad. The treatment of the disease is mainly expectant and supporting. The eruption on the face is treated by the application of a solution of nitrate of silver ℈j to ℥j.

J. J. Reid, M.D.

Pregnancy Complicated by a Fibroid Tumor of the Uterus.

Ed. Med. and Surg. Reporter:—

I herewith send you the report of an autopsy made upon a patient with the following history:—

On the 31st of December, 1881, I was called to see Maggie K., aged thirty-six years; single. I found her in a semi-unconscious condition, very restless, as though suffering considerable pain; her pulse weak and 120 per minute; action of the heart regular, but somewhat labored; mouth firmly closed, and was unable to swallow or speak; there were no convulsions. From what meagre history I could gather from those around her, found she had been in this condition for twenty-four hours before I saw her, that she had been treated for a tumor of the uterus; that she had been in ill health for several months; had not menstruated for two or three months, and that she had considerable vomiting, especially in the morning.

I made a vaginal examination, and taking into consideration the history of her case, came to the conclusion that she was pregnant, and that these symptoms might have been produced by some medicine taken for the purpose of producing abortion. I endeavored to get her to swallow some medicine, but she seemed too unconscious for that, and I did not succeed.

Being at the house of a stranger, I ordered her removal to the Mercy Hospital, this city, which was done, where she died the following afternoon, twenty-four hours after my first visit. The cause of her death being rather obscure, the coroner of this city was notified, who ordered Drs. James McCann, Joseph N. Dickson, and myself to make a post mortem examination of the body, which we did the next day, about twenty-four hours after death, when we found the following state of affairs: Post-mortem rigidity well marked; body well nourished; no marks of external violence. On opening the abdominal cavity several tumors of the uterus were discovered; one on the right iliac fossa, firmly adherent and dipping into the pelvis, very resisting and somewhat nodulated; another, of smaller size, a fluctuating tumor, which was firmly attached to the first and slightly overlying it to the left, being firmly adherent to the sigmoid flexure of the colon, the bladder, and pelvic fascia.

On dividing some of these adhesions they proved to be the round and broad ligaments of the uterus. After dissecting out this tumor and passing a probe into it through the canal of the uterus, and laying it open, it was found to be the uterus, containing a fœtus of about nine weeks.

The right tumor, upon incision, was found to be a solid fibroid, and in size about six by four inches in diameter. The right ovary was atrophied, but the left seemed in a fair condition of health.

The stomach contained about eight ounces of a dark, grumous, coffee-colored liquid. The mucous membrane at the cardiac end was thrown into rugæ, and separated readily from the submucous tissue. The pyloric end gave evidence of rather intense inflammation. The heart was normal in size and external appearance; on opening the left cavities, found the muscular structure, valves and internal lining membranes normal, but attached to the border of the mitral valve was a firmly organized, fibrinous clot, about four inches long and extending from the ventricle into the aorta. The semilunar valves of the aorta were perfect in structure. On section of the right side of the heart, the muscular structure, valves and internal lining membrane were here also found normal. But here another clot was found, not as firmly organized in the vena cava as in the right auricle and ventricle. This same clot nearly filled the auricle, extending through the auriculo ventricular opening, attached to the tricuspid valve and forming a clot in the right ventricle, which extended into the pulmonary artery to its bifurcation, and was, in size, nearly the capacity of the artery. The spleen was small and of normal structure. Kidneys large and in a condition of fatty degeneration, the structure being very much softened. The bladder contained about eight ounces of urine. Liver normal in structure and size, but very highly congested.

The case is certainly an interesting one, as it shows that a fibroid tumor of the uterus will not prevent pregnancy. As to the cause of her death; she had badly diseased kidneys. Were the symptoms of the last two days of her life produced by uræmic poisoning and subsequent heart clot? or was death produced by some irritating emmenagogue taken in an over dose? The stomach indicated a high stage of irritation, but analysis of its contents gave negative results. Oil of savine might have been taken, as it cannot be detected by any odor and is said to produce paralysis of the heart and heart clot, so well marked in this case. The verdict of the coroner's jury was that: "The said Maggie K. died from blood clots." About as intelligent a verdict would have been that she died for want of breath.

Pittsburgh, Pa. D. A. Hengst, M.D.

Extirpation of Thyroid Gland by Enucleation.

Ed. Med. and Surg. Reporter:—

In the *Record* of December 31st, last, there is a brief account of the excision of the thyroid gland, by Mr. Whitehead, of the Royal Manchester Infirmary, with the observation, "That it may be classed among the notable operations of surgery." A similar operation having been performed at the St. Mary's Hospital, in this city, with good results, I send you notes of same.

Gertrude Baker, aged three years, having a tumor involving the thyroid gland; first noticed about a year since, and for the last few months developing very rapidly, and becoming so large as to interfere with respiration.

Operation Dec. 6th, 1881, by Dr. Wm. A. Byrd, assisted by Doctors J. C. Hearne, of Hannibal, Mo., M. Rooney, House Physician, J. B. Shawgo, and G. W. Connell, of Quincy. Loss of blood

was moderate, and recovery rapid; the closing of the large denuded surface being hastened by skin-grafting. Weight of tumor eight ounces. Discharged December 22d.

A parotid gland was removed from Andrew Villslagh, by the same operation, followed by rapid recovery, and very slight facial deformity, May 10th, 1881.

Dr. Byrd proposes to give a full account of these operations as soon as practicable, illustrated from photographs.

Quincy, Ill. G. W. CONNELL, M.D.

NEWS AND MISCELLANY.

Dr. Joseph F. Edwards

Has accepted the position of assistant editor of the MEDICAL AND SURGICAL REPORTER. Dr. Edwards is already known to the profession through the *American Specialist*, of which he was editor last year, and also by his various works on "How a Person Afflicted with Bright's Disease Ought to Live," "Constipation," "Dyspepsia," "Malaria," etc. We can promise our readers that they will have a constantly improving journal, through his energy and knowledge.

Vital Statistics.

From the City Registrar's office of Providence, R.I., we note the following interesting statistics: Total death rate for 1881, 20.45 per 1000. Among whites, 20.13 per 1000; colored, 29.34 per 1000. American parentage, 20.67 per 1000. Foreign parentage, 20.26 per 1000. Thirty per cent. of all the deaths were fifty years of age or over. Greatest number of deaths occurred in August. The following point is very noteworthy: "There were 2307 persons vaccinated at the office of the Superintendent of Health (964 more than in 1880) and 1984 certificates of vaccination given to school children. The population is 104,000. Now, there has been no death from smallpox in Providence since July, 1875, and only one death since 1873." There were 16 deaths over 90, and one over 100 years of age.

Guiteau's Opinion of Experts.

That Guiteau possesses a very level head on some points, at least, is shown by the following remarks made by him to the court: "That's a first-class decision, Judge; that's all I want to get before the jury—what I said at that time relative to the causes that impelled me upon the President. As for the rest I don't care a snap. I would not give fifty cents a bushel for this expert testimony. If I had money enough I could get fifty of the best experts in the country to swear that I am as crazy as a loon. That's just how much that kind of evidence is worth."

Death Under Chloroform and Ether.

—The London *Lancet*, of December 31st, 1881, says: Last week a patient died at the Great Northern Hospital, while under the influence of a mixture of chloroform and ether, administered preparatory to the removal of the nail of the great toe. The anæsthetic was given on lint, and the operation was completed, when it was discovered that the pulse had ceased, and the patient succumbed in spite of every effort adopted to restore animation.

Items.

—The chair of Natural History, at Edinburgh, has been offered to Dr. Francis M. Balfour, F.R.S., author of the treatise on Comparative Embryology.

—Mr. L. O. Howell, Jr., has submitted to the Board of Health of this city a code of laws for the regulation of plumbing and drainage. The matter has been referred to the Sanitary Committee.

—The Executive Committee of the National Board of Health, in session on January 20th, officially declared smallpox to be epidemic in the United States, and appropriated two thousand dollars to prevent its spread in the District of Columbia.

—Domestic physiology: "Eight parts in ten of the blood consists of pure water; do you remark that, Mrs. Tooflorida?" "I do, sir, and if it's your own blood you are talking about, Mr. Tooflorida, take my word for it the other two parts consist of whisky."—*New York Commercial Advertiser.*

MARRIAGES.

LOGAN—OLMSTEAD.—On the evening of Dec. 29th, 1881, in the First Presbyterian Church of Scranton, Pa., by Rev. S. C. Logan, D.D., Harry V. Logan, M.D., eldest son of the officiating clergyman, and Miss Mary M. Olmstead, only daughter of Mr. Richard W. Olmstead, all of Scranton, Pa.

LYNTON—SMITH—Dec. 15th, 1881, by Rev. S. S. Wylie, at the residence of D. R. Smith, Harry M. Lynton, M.D., of New York City, and Miss Saidie E., eldest daughter of D. R. Smith, of near Middle Spring, Pa.

MILLER—FOREPAUGH.—On Wednesday, January 11th, by Rev. George Dana Boardman, D.D., Dr. S. T. Miller, of Paulsboro, N. J., and Jennie Forepaugh, of Philadelphia. No cards.

PRATT—CATHCART.—On Thursday, December 29th, 1881, at the residence of the bride's father, in Concord, Mich., by Rev. C. P. Quick, Dr. E. B. Pratt, of Brownville, N. Y., and Miss Sara E. Cathcart, of Bay City, Mich.

RUGG—HAGER.—In Proctorsville, Vt., Dec. 28th, by Rev. William H. Rugg, of Perkinsville, David F. Rugg, M.D., of Hartland, and Julia A. Hager of Proctorsville.

WEBB—VANDERBILT.—In New York, on Tuesday, December 20th, 1881, at St. Bartholomew's Church, by the Right Rev. the Bishop of New York, the Rev. Dr. Cooke, and the Rev. Dr. Howland, Dr. William Seward Webb and Lila Osgood, daughter of William H. Vanderbilt.

DEATHS.

BARRY.—In Brooklyn, at the residence of his father-in-law, on Friday, Jan. 6th, Dr. Robert A. Barry, of New York, in the 58th year of his age.

BEESLEY.—At Dennisville, N. J., December 13th, 1881, Maurice Beesley, M.D., in his 77th year.

MOORE.—On the 11th inst., at Chicago, Ill., Dr. Jos. C. Moore, in the 37th year of his age.

NEEDHAM.—Dr. W. C. H. Needham, State Senator of Ohio, of the Gallipolis district, died recently, of typhoid pneumonia.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

EXTRAVASATION OF URINE.

By FESSENDEN NOTT OTIS, M.D.,

Professor of Diseases of the Genito-urinary System in the College of Physicians and Surgeons, New York.

GENTLEMEN:—On account of failure of the usual conveyance, it was impossible for many of you to attend my last clinic at Blackwell's Island. One of the cases presented on that day was of unusual importance, so much so that it appears to me worthy of occupying a share of your attention to-day, especially as we shall probably have an opportunity of watching its subsequent development. I will, therefore, give you its history up to the present time.

On Tuesday last I went to the Island to make my ordinary rounds, and inquired if there were any new cases of importance to be looked after. Was informed there was a patient, a man, who had a slight swelling in the perineum, and had had retention of the urine, which the house surgeon had easily relieved; the swelling was being poulticed. From having had some interesting experience with slight perineal swellings, I was interested to see the case. Examination showed, not only a perineal swelling, but some œdema of the scrotum. The scrotal swelling, which had come on within an hour or two, was translucent, rosy in color. The patient complained of great difficulty in passing his water. When I asked him to urinate the urine came away in drops. On further inquiry I found that he had been the subject of gonorrhœa several times, but he had never had a stricture, nor any recent gonorrhœal trouble, nor any difficulty with urination until within a few days. He had some fever, which was attributed to the perineal inflammation. When I saw him the temperature was 102.5° Fahrenheit, and the pulse was about 115 or 120. The patient was informed that it was necessary to open an abscess which I believed was present in the perineum, although there was very little fluctuation or other positive evidence. He declined, however, to have anything done, believing that he was doing very well; he insisted that he was passing his water better than he had done, and he did not see any reason why he should be operated on, and he did not propose to be operated on. I urged him, by all the considerations which I could bring to bear, to allow me to operate on him, assuring him that a very grave accident had occurred; that there had been an abscess of the penis, which had opened into the urethra; that through this opening urine had found its way into the tissues of the scrotum; that this innocent looking œdema of the scrotum was nothing more nor less than the result of urinary infiltration which threatened destruction of important parts within a very few hours, and that the extravasation was likely to extend to the tissues of the abdomen. I presented to him, in as strong a light as possible, the dangers attending delay, but could not prevail upon him to allow me to operate. His only reply was, that he would not be operated upon to-day. Having no other alternative, I passed a soft rubber catheter into the bladder and left it, with instructions that when, through the advance of the infiltration, the patient should be brought to consent, an operation would be performed; for, of course, as long as he was in his right mind, we could not compel him to submit to an operation, and besides there

was a possibility that an opening might occur through the external parts, by suppuration, and so afford relief.

The next morning the house surgeon came to my office with word that the size of the scrotal tumor had increased considerably; that the tissues were becoming of quite a dark red, and that swelling had taken place above the pubes. He also stated that slight redness covered an area of five or six inches square in the integument of the right groin. After arriving at the hospital, I found the scrotum fully six inches in its long diameter and nearly five in the transverse—pitting easily on pressure. The perineal swelling was somewhat more prominent, very firm, and very slight if any sense of fluctuation imparted to the touch. The patient was etherized and a grooved staff, No. 15, was passed easily into the bladder. This was held firmly in the median line, by my friend, Dr. Sturgis, who kindly assisted in the operation. Then passing my finger into the rectum, in order to avoid wounding the gut, I made my perineal incision two and a half inches in length, and deeply, until the sound was reached. Almost at the first stroke of the knife there was a gush of fetid pus, at least two ounces.

I introduced a broad director alongside the sound and on into the bladder, and then, removing this instrument, passed a large catheter along the director into the bladder and removed the director. A large soft catheter was then introduced into the bladder through the perineal opening, in order to keep the viscus well drained. In passing, allow me to remark that this is the plan I always follow in perineal sections, thus keeping the tissues free from danger of subsequent infiltration of urine. I made five incisions into the swollen scrotum, from two to four inches in length, extending through the superficial fascia and cellular tissue, down to the tunica-vaginalis, and by a little compression with my hands the urine and serum poured out freely, and the tissues were emptied, to a very considerable extent, of this irritating material. Oakum smeared with vaseline was then put into the cuts, a bandage applied, and the patient was carried to his bed. To-day, the day after the operation, I am informed that the patient is quite comfortable; the temperature has gone down two degrees, the color in the groin is fainter, the swelling has not increased.

This trouble might have gone on further, and, as usually occurs in cases of extravasation, we should have infiltration of urine in the groin and integument over the abdomen, requiring further incisions to be made. From the report of the case to-day, however, I trust this will not be necessary.

A few words now with regard to the manner in which this accident occurs. The urethra is studded with little follicles or racemose glands, some of which are at the bottom of a little canal, or canaliculus, and from these the lubricating fluid of the urethra is in great measure derived. There is notably one found in almost all urethræ, on the superior surface of the canal, about half an inch from the meatus externus, the lacuna magna, which is often large enough to admit the end of a small-sized probe. These little secreting glands at the bottom of depressions, which are more numerous in some urethræ than in others, sometimes become inflamed independently of inflammation of the surrounding tissue. That is to say, there sometimes occurs trouble localized in a single one of these depressions, and when this is the case, it is usually the result of a stricture of large calibre; a stricture which is just sufficient to form a slight obstruction, behind which pus or other material may lodge and keep the parts in an abnormal condition, ready to take on inflammation. Such is the explanation of an accident like that which occurred in our patient, as given by authorities who have paid particular attention to this subject. Inflammation having been thus excited in one of these follicles, suppuration takes place, pus burrows along, sometimes a distance of half an inch or an inch; sometimes it makes its escape externally in the shortest direction. In any case we have a passage formed through the urethra into the tissues, and into this urine readily finds its way, sometimes, however, in so small quantity that it simply gets up a little accumulation of plastic material, which finally forms a small nodule and stops the further progress of the trouble. Again, the opening may be larger, and urine may find its way into it in greater quantity, and cause active inflammation in the tissues, forming an abscess, through which extensive infiltration may take place.

This subject is one of such great importance that I will be obliged to complete my remarks on a future occasion, the first part of this hour having been occupied by the presentation of other cases. Owing to the fact that writers have said a very great distinction should be made between the little bunches which result from slight departures from the urethra and an abscess the result of urinary extravasation, the subject of perineal swellings has come to be very greatly misunderstood. I insist upon it that no difference exists in the

nature of the two cases, and whenever a swelling of the perineum occurs independent of an immediate injury, or a furuncular trouble, we may be sure that in ninety-nine cases out of a hundred it is the result of follicular penetration of the urethral canal, from the causes previously stated, and that it will go on to the formation of an abscess of greater or less size; and we cannot tell in any case, whether what appears to be a small affair is going to remain so, or whether it is going on to the destruction of a large amount of tissue. Some of the most innocent appearing cases have gone on rapidly, within a few hours, to result in infiltration of urine and speedy death of the patient.

(To be Continued.)

COMMUNICATIONS.

ON THE THERAPEUTIC USE OF JABORANDI AND PILOCARPINE IN EYE DISEASES.

BY M. LANDESBERG, M.D.,
Of Philadelphia.

The results of my first trials with jaborandi and pilocarpine, published in numbers 298 and 299, vol. IX, of the Philadelphia *Medical Times*, and in vol. VIII, 1, of Knapp's *Archives of Ophthalmology*, have justified me in endorsing the important therapeutic value of this new remedy, and in claiming for it a superiority over all hitherto known absorbent remedies in instances of serous effusions, intraocular hemorrhages and opacities of vitreous. The diversity of opinion which still exists among the general as well as the special profession in regard to the therapeutic value of the drug; the objections which are often raised against its use, on account of the unpleasant after effects which so frequently follow its administration, prompt me to give a further account of my experiences gained from the continued use of jaborandi and pilocarpine, in the various forms of eye diseases. But in order to show the intrinsic properties of this remedy in all purity, I shall give notes only of such cases in which I employed either jaborandi or pilocarpine, without the simultaneous use of any other medicine.

(A) *Extract of Jaborandi* has been used in the following eye affections:—

1. *Parenchymatous keratitis.* There was no effect whatever in any of the ten cases (eight children and two men) in which the remedy was administered for two succeeding weeks. The morbid process ran its course as if no treatment had taken place at all.

2. *Panophthalmitis*, following discision of cataract in one case, and linear extraction of cataract in another. The treatment resulted in relieving the severe pain and in abating somewhat the symptoms of inflammation. But it had not the slightest effect upon the course of the morbid process.

3. *Hemorrhages into the anterior chamber and vitreous*, consequent upon a blow on the eye, in seven cases. Vision was reduced to perception of light only. In three patients, ten doses of jaborandi, in four patients, fifteen doses, taken within two weeks, brought about perfect recovery.

4. *Irido-choroiditis, with opacities of vitreous*, in three women between the ages of eighteen and twenty-six years. In the first two cases, sixteen doses of jaborandi, taken within three weeks, restored the normal condition of the vitreous and brought vision from $\frac{20}{70}$, resp. $\frac{15}{40}$, to $\frac{20}{20}$, resp. $\frac{15}{20}$. In the third case, in which mercurial treatment and iridectomy did not check the morbid process, seventeen doses of jaborandi, taken within four weeks, resulted in a perfect cure. Vision increased from $\frac{20}{70}$ to $\frac{20}{40}$. Only two small flocks were left in the vitreous.

5. *Irido-choroiditis serosa, with opacities of vitreous*, in two cases. In the case of a shoemaker, fifty years old, ten doses of jaborandi, taken within three weeks, brought vision from $\frac{20}{70}$ to $\frac{20}{30}$, and made vitreous perfectly transparent. In the other case, of a woman of forty-eight years, in whom vision was reduced to counting fingers at 3′, fifteen doses of jaborandi, taken within three weeks, brought about perfect recovery. Vision increased to $\frac{20}{30}$, and opacities of vitreous vanished entirely.

6. *Æquatorial choroiditis with circumscribed choroidal atrophies, diffuse infiltration of the retina, and opacities of vitreous.* The vitreous humor had the form of a bunch, composed of numerous large, thick tufts, which spread, fan-like, into the space of the vitreous, veiling almost totally the background of the eye. Vision was reduced to counting fingers at 5′. Patient, workman's wife, twenty-eight years, had remarked for eighteen months the gradual decrease of vision in her left eye.

After the fifth dose of jaborandi V. was $\frac{20}{50}$. Opacities of vitreous were considerably thinner and more transparent. Some fascicles of the bunch had totally vanished; others had become very thin; and still others had dissolved into small, roundish, star like bodies, which moved in the vitreous like a shower of shooting stars.

After the tenth dose of jaborandi V. was $\frac{20}{40}$, and Jaeger 1. Vitreous contained only some

very fine opacities and one large membranous flock.

After the fourteenth dose of jaborandi, V $\frac{20}{40}$. Only few fine opacities of vitreous are to be seen.

7. *Neuro-retinitis*, in two cases:—

In the first case, of a servant girl, 36 years old, the affection developed consequent upon the suppression of the menstrual flow, which had been caused by taking a cold. Vision of either eye was reduced to $\frac{20}{70}$. Fifteen doses of jaborandi, taken within three weeks, brought about perfect recovery.

In the second case, of a woman of 45 years, whose monthlies had stopped five years previously, the affection, gradually progressing, had reduced vision to $\frac{20}{200}$ in the right eye, and $\frac{20}{70}$ in the left one. Eighteen doses of jaborandi, taken within four weeks, improved the vision of the left eye to $\frac{20}{40}$, but had no effect whatever upon the condition of the right eye. The final issue of the latter was atrophy of the optic disc.

8. *Genuine atrophy of the optic disc*, in three cases:—

The first case was of a factory girl, 22 years old, whose eye affection developed in the course of erysipelas of the face and head. The right eye showed complete amaurosis. The left eye had V $\frac{20}{70}$. Eighteen doses of jaborandi, taken within twenty-five days, restored vision of the left eye to $\frac{20}{30}$. There was no effect upon the right eye.

In the second case, of a shoemaker, 40 years old, without obvious cause, eighteen doses of jaborandi, taken within four weeks, had the result to bring vision from $\frac{20}{70}$ resp. $\frac{20}{200}$ to $\frac{20}{40}$ resp. $\frac{20}{70}$.

In the third case, of a merchant, 51 years old, the affection had set in in consequence of an injury of the head, received in falling from the steps. Nineteen doses of jaborandi, taken within thirty days, had the effect of improving the sight of the right eye from counting fingers at 3′ to counting fingers at 6′, and the sight of the left eye from $\frac{20}{30}$ to $\frac{20}{30}$.

9. *Retinitis e morbo Brightii*, in the case of a saloon keeper, 47 years old. Seventeen doses of jaborandi, taken within thirty-one days, brought vision of the right eye from $\frac{20}{70}$ to $\frac{20}{40}$, and of the left eye from $\frac{15}{70}$ to $\frac{20}{30}$. The optic discs became less choked. Most of the hemorrhages were resolved. General constitution improved.

10. *Detachment of the retina*, in four cases:—

Of the three cases of detachment of the retina in consequence of progressive myopia, the treatment with jaborandi had no effect whatever in two instances, and a moderate result only in one case. In the fourth case of detachment of retina, which had been caused by hemorrhage between choroidea and retina, consequent upon a blow upon the eyeball, complete recovery was obtained by nine doses of jaborandi, taken within two weeks.

(B) *Muriate of pilocarpine* has been used in the following affections:—

1. *Paralysis of the extern muscle of the right eye*, consequent upon exposure to cold, in two cases. There was complete recovery after five resp. eight subcutaneous injections of pilocarpine.

2. *Hemorrhage into the vitreous*, occurring spontaneously seven months after a successful linear extraction of cataract. When I saw the patient, five days after the occurrence, he counted with this eye fingers at 5′ distance. The background of the eye could not be seen. Seven injections of pilocarpine, administered in the course of two weeks, brought about complete resorption of the hemorrhage, and restored vision to $\frac{15}{40}$.

3. *Central retinitis, with large, floating opacities of vitreous*, caused by a blow upon the right eye. Twenty-four hours after the accident, examination showed V. $\frac{15}{70}$ with concave $\frac{1}{3}$, Jaeger 3. Anterior chamber shallow; tension somewhat diminished. One application of Heurteloup gave no improvement. After seven subcutaneous injections of pilocarpine, there was V. $\frac{15}{40}$ with concave $\frac{1}{6}$, Jaeger 2. There is only one large flock in the vitreous left. All other opacities have vanished. After thirteen injections, V. $\frac{15}{20}$ with concave $\frac{1}{8}$ (the degree of myopia as had been before the injury), Jaeger 1. Anterior chamber and tension normal; serous infiltration and swelling of retina near macula lutea entirely vanished; vitreous perfectly clear. After a minute research one small, oblong opacity of vitreous, which has the shape of a spermatozoön, is discovered.

4. *Large, dense opacities of vitreous* in a lady, whose right eye had been struck by the elbow of her child. Eleven subcutaneous injections of pilocarpine effected total resorption of the opacities and restored vision from $\frac{15}{50}$ to $\frac{15}{20}$.

5. *Chorio-retinitis, with opacities of vitreous*, in consequence of progressive myopia, in a lady of fifty-two years of age. There was:—

Right Eye. M. $\frac{1}{3}$ S. $\frac{15}{50}$. Numerous large flocks in vitreous. Intense sclereolasia posterior. Large choroidal atrophies. Œdema of the retina and large, milky patches along the vessels.

Left Eye. Central vision totally abolished. Counts fingers at 2′ distance, peripherically outside. Atrophy of the retina, over which are scattered patches of pigment, extravasations and

exudations, which hide the vessels. The region of the macula lutea is of milky appearance. Vitreous contains filiform opacities. Fifteen subcutaneous injections of pilocarpine had the following effect:—

Right Eye. M. $\frac{1}{3}$–$\frac{1}{2}$. V. $\frac{15}{30}$. Only two small flocks in vitreous left. Œdema of the retina and milky exudations vanished.

Left Eye. Vision slightly peripheric. Counts fingers at 12′. Reads Jaeger 13. Extravasations and exudations vanished. Macula lutea is covered by a patch of pigment. Vitreous is clear.

6. *Detachment of retina.* In three cases of detachment of retina of long standing pilocarpine was of no avail.

In one case of recent detachment of retina, in a patient of 51 years of age, whose healthy eye showed myopia $\frac{1}{8}$, the treatment with subcutaneous injections of pilocarpine yielded a very favorable result, also the latter did not remain stationary. The retina reattached almost entirely, and central vision increased from $\frac{15}{100}$ to $\frac{15}{40}$. The relapse, after about four months, was again successfully combated by the same treatment. But when the detachment of retina set in for the third time, after an interval of nearly five months, patient acquiesced in his fate.

In another instance of recent detachment of the retina in both eyes, the improvement in the morbid condition of either eye was very remarkable after seven injections of pilocarpine. But patient withdrew from further treatment.

7. *Hemorrhagic retinitis* in the left eye of a boy of eight years of age. Vision was $\frac{15}{20}$; Jaeger 5; fixation somewhat peripheric; central scotoma; field of vision normal; retina occupied by numerous extravasations of blood, of the size of a pin's head. Large hemorrhagic patch between optic disc and macula lutea. Vitreous clear. The appearance of a dark spot before the eye, about three days ago, had first attracted the attention of the boy to the present trouble.

There is no assignable cause of the affection; general health is good; respiratory and circulatory organs are normal. There is no symptom whatever of hemorrhagic diathesis.

Eleven subcutaneous injections of pilocarpine, made within three weeks, effected a total resorption of the small hemorrhages. The large extravasation broke into numerous small dots. Vision became $\frac{15}{40}$, and fixation central.

8. *Retinitis pigmentosa* in the following case: B., printer's son, nine years old, was brought to me on account of impairment of vision and of hearing, which had gradually developed in the course of the last two years; general health has always been good and mental capacities have been normal.

The external appearance of the eyes and ears are normal; V. R. $\frac{20}{70}$; Jaeg. 7; V. L. $\frac{15}{70}$; Jaeg. 7; field of vision shows concentric limitation in the peripheric parts. This limitation is about twice as large in a dark room lighted by gas, than at daylight. On asking the patient, I find that the boy has great difficulty to move in the dark of the evening.

The ophthalmoscope reveals: Optic discs somewhat flat, slightly grayish; papillary region distinct; arteries contracted; veins normal. In the peripheric parts of the retina there is a continuous network of fine, star-shaped patches of pigment, deposited along the vessels; maculæ luteæ are distinct.

With the right ear patient hears whispering at 8′, with the left at 6′ distance; medium loud voice is heard at 12′. The membranæ tympani are somewhat opaque. Passage for ear-douche is good. No noises.

There is no consanguinity between the parents, and no hereditary tendency in the respective families. Syphilitic taint is denied by both parents. The boy is the only child born after ten years of married life.

Ten subcutaneous injections of pilocarpine, made within twenty-five days, had the following effect:—

V. R. $\frac{20}{40}$, Jaeger 2. V. L. $\frac{20}{50}$, Jaeger 4. Field of vision free by daylight; by gaslight somewhat limited in its peripheric parts. Optic discs are of somewhat reddish hue. The pigmentary deposits are flatter, fainter in hue, and transparent. Hemeralopia is considerably improved. The condition of the ears is unchanged.

9. *Double optic neuritis*, in the following case:— Miss G., twenty-five years old, had noticed a considerable decrease in the vision of the right eye, the day after the right side of the face had been exposed to a strong, cold draught. The sight failed, consequently, so rapidly, that when I saw patient, on the third day after the occurrence, the condition was as follows:—

Right Eye. Outside appearance normal. The movements of the eyeball outside and upward, the gently pushing of the latter into the orbital cavity, are painful; the pain had been more intense in the first two days. The region around the foramen supra-orbitale is very sensitive to the touch. Vision is reduced to counting fingers at 10′ to 12′ distance. The fixation is somewhat peripheric. Field of vision is slightly narrowed in the upper periphery. Reaction of pupil is sluggish. Tension is normal. Refracting media

are clear. Optic disc is of reddish-gray color, prominent, opaque and swollen. Its vessels are hidden by the serous infiltration, which extends over the peripapillary region. Small hemorrhagic patches are scattered over the optic disc, and one large oblong extravasation of blood covers the peripapillary part of the inferior branch of the ophthalmic vein. The inner border of the optic disc is occupied by a slightly prominent grayish plaque. The arteries are contracted, the veins are engorged, dark-red and tortuous.

Left Eye normal. General health has always been good. Percussion of the head is not painful. Mental capacities are unimpaired. No headaches and no syphilitic taint. Circulatory and respiratory organs are normal.

After five subcutaneous injections of pilocarpine there was V. $\frac{15}{200}$, Jaeger 9. Fixation somewhat peripheric. Perception of colors normal. The movements of the eyeball, the pushing of the latter into the orbital cavity, are painless. Pressure on the exit of the supra-orbital nerve causes only a slightly uneasy sensation. The swelling of the optic disc is somewhat diminished. The small hemorrhagic patches have vanished.

After ten injections of pilocarpine there was V. $\frac{15}{70}$, Jaeger 5. Fixation slightly peripheric. Field of vision normal. All traces of pain vanished. The œdema of the optic disc considerably diminished. The large hemorrhagic patch partly resorbed. The grayish plaque flattened.

No further improvement after the fifteenth dose. Heurteloups and iodide of potassium, to which I resorted, were of no avail.

During a further observation of about three months, the optic disc remained slightly swelled, dusky, and of bluish-gray color. The vessels were veiled by a delicate, diffuse opacity; the peripapillary region was indistinct. The arteries were thin, the veins somewhat engorged and tortuous. Vision decreased to $\frac{15}{100}$, Jaeger 8.

10. *Genuine atrophy of the optic disc, with central scotoma,* in two cases:—

In the first case, of a merchant, forty-eight years of age, fifteen subcutaneous injections of pilocarpine, made within twenty-three days, brought vision from $\frac{15}{200}$ to $\frac{15}{30}$ in either eye.

In the second case, of a merchant, fifty years of age, nineteen subcutaneous injections of pilocarpine, made within a month, brought vision from $\frac{15}{200}$ to $\frac{15}{50}$ in the right eye, and from $\frac{15}{100}$ to $\frac{15}{30}$ in the left eye.

11. *Amaurosis of both eyes,* caused by a uræmic attack in the course of scarlatina, in the case of a girl of eleven years of age. Nephritis developed on the twentieth day of the affection, in consequence of exposure to cold. After a uræmic attack, total blindness set in in both eyes. Perception of light reappeared after twelve hours, and the sight improved spontaneously in the following two days, so far that the patient was able to distinguish the features of her parents. When I saw the girl, on the eighth day after the occurrence, she counted fingers with either eye at 2′ distance. Quantitative perception of light was good in all directions of the visual field. Pupils were somewhat dilated, but of normal shape and reaction. Refracting media and tension were normal.

Ophthalmoscopic examination was negative. There was some hydrops around the ankles. Urine contained albumen.

After the second injection of pilocarpine vision increased to $\frac{20}{70}$, and became $\frac{15}{20}$ in either eye after the ninth injection. Hydrops and albumen disappeared.

12. *Chronic Scleritis and irido-choroiditis, and opacities of vitreous* in the left eye, in the case of a waiter of twenty-seven years of age. The affection had lasted for about three years. The different kinds of treatment to which the patient had been subjected had afforded but little relief. Eighteen subcutaneous injections of pilocarpine, administered within five weeks, resulted in clearing up the vitreous, in improving the vision from $\frac{10}{200}$ to $\frac{15}{70}$, and in bringing the morbid process to a stand-still.

General Remarks.—Either preparation was administered two or three hours after a light supper had been taken, the patient being in bed, covered with a blanket. Jaborandi was given in warm tea, in doses which varied from fifty drops to four teaspoonfuls. Of forty-three adults whom I treated with jaborandi, the desired effect was produced with fifty drops in five; with one teaspoonful and a half in ten; with two teaspoonfuls in twenty; with three teaspoonfuls in five; and with four teaspoonfuls in three patients. The effect took place in about fifteen to thirty minutes after the ingestion of the drug, beginning with salivary secretion; perspiration followed within ten to thirty minutes afterward. In no instance a reverse condition was observed, and in no case the absence of either effect noted. Salivation lasted for about one hour and a half to two and three hours; perspiration subsided earlier. There was no ill effect whatever in ten patients; in seven patients the unpleasant after symptoms were very considerable; in the others they were but slight.

My experience in the use of jaborandi, gained in adults, totally failed when I began to try the remedy in children. The first child which I treated with jaborandi was a girl of seven years, who suffered from parenchymatous keratitis of both eyes. The mother was ordered to give at first thirty drops, and eventually to raise the dose to sixty drops. But even the latter dose failed to produce any effect. On two teaspoonfuls the skin became somewhat moist. A full benefit was only obtained by injection of four teaspoonfuls of the drug. Perspiration was copious for about an hour. Salivation was almost absent. There were no unpleasant after symptoms whatever. In the other seven cases of parenchymatous keratitis, observed in children between seven and twelve years of age, I had also to recur to high doses of jaborandi in order to produce the desired effect. In four children between nine and twelve years the dose was four teaspoonfuls; in three children, between seven and nine years, five teaspoonfuls. Salivation was absent in three children, and but very slight in four. Perspiration was less copious than in adults, and of shorter duration. The ill after-effects were very slight. Vomiting occurred only once, in a child which had taken a large supper before the ingestion of jaborandi. Nausea occurred in two children. The only inconvenience generally felt was pain in the abdomen.

The effective dose for subcutaneous injections of pilocarpine, in adults, varied from $\frac{1}{4}$ to $\frac{3}{4}$ of a grain. Salivation generally set in within two to ten minutes; in several cases, however, instantaneously—before I had time to withdraw the needle. Perspiration followed after, about two to ten minutes. The duration of salivation was longer than perspiration; the latter kept on for an hour to two hours, the former continued for half an hour to an hour longer. The action of the drug began, in all instances, with increase in the pulse-rate and mostly with congestion to the head. The respiration was accelerated, and in several cases difficult. In a few instances there was dyspnœa. This stage was the most unpleasant one to the patients. But these phenomena vanished as soon as salivary secretion made its appearance, and general easiness took place with the occurrence of perspiration. In the course of the process there was a slight fall in the temperature of the body; the patients felt chilly and they required warmer covering.

Of twenty-seven adults in whom I used subcutaneous injections of pilocarpine, the after symptoms were very stormy in two. Vomiting and nausea occurred after every injection, and the other inconveniences were very severe. In five patients there were no unpleasant after-effects at all. In the other patient the ill after-effects were but slight, and easily borne. Slight gastric catarrh was generally a consequence of the treatment, but it was entirely wanting in a few instances.

Inflammation of the subcutaneous tissue around the point of injection occurred only in one lady patient. The inflammation set in after every injection, but it was very slight, and subsided either spontaneously or on warm poultices.

In children, I had to administer from half a grain to one grain of pilocarpine, in order to gain a full effect. Perspiration was copious; salivation but moderate. The after symptoms either very slight or totally wanting. The children had not the slighest aversion to the treatment.

1912 *Arch Street, Philadelphia.*

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC BY JOHN ASHHURST, JR., M.D.,

Professor of Clinical Surgery in the University of Pennsylvania.

Reported by Wm. H. Morrison, M.D.

FRACTURE OF THE SHAFT OF THE FEMUR; FRACTURE OF BOTH BONES OF THE FOREARM; FRACTURE OF THE NECK OF THE FEMUR; TENOTOMY OF THE TENDO-ACHILLIS AND PLANTAR FASCIA.

Gentlemen:—I have the opportunity, at the beginning of the session, to show you several cases of fracture. These are cases that you will meet constantly in practice, and it is of extreme importance that you should be entirely familiar with their treatment, both for your own comfort and for that of your patients.

Fracture of the Shaft of the Femur.

This young man has sustained a fracture of the shaft of the thigh bone. He was walking along the top of a train of cars, and falling between two of them, he received a fracture about the middle, or a little below the middle, of the left femur.

This particular form of injury, fracture of the shaft, is, in adults, often the result of indirect violence. In children, the injury usually results from direct violence, as from a blow, or from a wagon wheel passing over the limb. This fracture often results from a fall upon the knee, or from a blow on the bent knee, in such a manner as to bring, as it were, the extremities of the bone together. A not unfrequent mode in which this injury is produced, is by a man sitting upon the platform of a car with his knee resting against the car in front. The cars suddenly come together, there is an approximation of the ends of the bone, and the thigh is broken. When it results from indirect violence, the line

of fracture is commonly oblique. In oblique fractures there is more marked shortening than in those which are transverse. In children, where the injury is the result of direct violence, the line of fracture is very apt to be transverse, and there is little shortening. I do not suppose that we shall find much shortening in this case, as extension has been applied for forty-eight hours. In measuring the thigh you should, in the first place, see that the pelvis is evenly elevated on both sides, and that the patient is lying squarely on his back. You can ascertain this by drawing a line from one anterior superior spinous process to the other, and then dropping a line perpendicular to this line, at its middle; the perpendicular line should, of course, come evenly between the limbs. We now have the patient squarely on his back, and if there is any difference in the length of the limbs we can ascertain it by measuring. The best points to use in measuring are the anterior superior spinous process and the corresponding internal malleolus. There is one source of fallacy: that is, one limb may naturally be shorter than the other. In a large number of persons one leg is shorter than the other. Now if a person whose right leg was naturally three-fourths of an inch or an inch shorter than the left sustained a fracture of the right leg, you can easily see that you could not derive much information from measurement. In this case the right leg measures almost thirty-four inches, while the left is not quite thirty-three inches. It is, of course, possible that the left leg was naturally an inch shorter than the right, but as we have the shortening on the side of fracture, the inference is that it is due to the fracture.

This is, perhaps, the most prominent symptom of fracture. Students are sometimes asked to give the most common symptom of fracture. The answer is "shortening." There are some exceptions to this rule; thus, in fracture of the patella, of the olecranon process of the ulna, and of the ensiform process of the sternum, you have lengthening, but with these exceptions, shortening is the rule, and is the most common symptom of fracture, and is particularly marked in fracture of the thigh.

Besides shortening, we have eversion of the foot. This patient has both feet about equally everted. If I ask him to invert the sound limb he does it very well, but when he attempts to invert the injured limb, he moves it very slightly, and if I try to invert it I give him pain. You must sometimes judge, not so much from the presence of eversion as from the absence of the power of inversion. Eversion of the foot occurs when there is fracture of any part of the thigh bone. It is particularly marked in fracture of the neck.

The explanation of this eversion is given differently by different authors. Some say that it is due to muscular action alone. Occasionally, in very rare cases, inversion of the foot is met with; these cases are explained by supposing that the muscles of the outer side of the limb are paralyzed. Mr. Erichsen gives this explanation.

It used to be said, without any very positive reason, that the eversion was due to the weight of the limb. This has been denied by those who believe exclusively in muscular action; but as in many other matters, the true explanation lies between these two extremes. Mr. Owen, an English surgeon, has performed the experiment, on the cadaver, of making a longitudinal section of the leg from the seat of fracture downward, and he has found that the outer side of the limb is the heavier, and that the centre of gravity lies in the outer side. So that by a mechanical necessity the foot is turned outward. Shortening and eversion are the two most important symptoms of fracture of the thigh.

Besides these, we have a symptom common to almost all fractures (but not to impacted fracture), *i.e.*, crepitus. I shall not put the patient in pain by trying to produce crepitus. Dr. Hughes distinguished it very clearly when the man was admitted. Sometimes you will fail to produce crepitus, unless you make extension. This is due to the fact that the ends of the bone may have become imbedded in the muscles and no part of the fragments be in contact. Of course, in all unimpacted fractures you have increased mobility.

There is another symptom to which I want to call attention, and that is slight tenderness and effusion in the knee joint. You see on this side of the thigh a slight abrasion, and you might suppose that the effusion was the result of direct injury, but such is not the case. Effusion into the knee joint is a characteristic symptom of all fractures of the thigh at or below the middle, and it is also met with in many fractures of the tibia. The explanation is interesting. The true explanation has been given by a French surgeon, Mr. Gosselin. It has been supposed to be due to direct injury of the joint. It often comes on some time after the injury. It was present in this case when the man was admitted, twenty hours after the injury. The correct explanation is this: at the seat of fracture, beside the bone being broken, there is great laceration of the muscles and cellular tissue, and much blood is thrown out. The blood gradually leaks down until it reaches the capsule of the joint; it does not enter the joint. That effusion is simply serous, synovial effusion. The blood reaches the outside of the capsule, there produces irritation, and a true synovitis is set up, as a result of this irritation. It is a mild form of subacute synovitis set up by the blood irritating the outer side of the capsule. Whenever you have synovitis, from any cause, you will have effusion into the joint.

I might call attention here to the way of distinguishing effusion in the joint from effusion around the joint. When I press the patella downward, I find that it floats. When I tap it, it at once rebounds. On the other hand, if the patella rested steadily on the femur, and there was no floating nor rebounding, I should feel sure that the effusion was extra-articular.

Here, then, we have the characteristic symptoms of fracture of the shaft of the femur: shortening, eversion of the foot, crepitus, increased mobility and effusion into the knee joint.

The treatment of fracture of the shaft of the thigh bone depends upon a consideration of these characteristic symptoms. There is shortening; you therefore need some means of extension. The older surgeons relied upon their hands to

make this extension, and upon splints to maintain it; but in modern time the weight extension has been adopted. It is applied in this manner. We first make what is called a stirrup, by means of a piece of board wider than the foot and a long strip of plaster that will extend from above one side of the knee around the foot piece and to above the opposite side of the knee. A short piece of plaster is placed on the inside of the foot piece, extending to each malleolus, in order to protect them. The two long strips are then applied in this manner to each side of the leg. Some surgeons carry the extension above the knee, but my own preference is to limit it below the knee, principally on account of this effusion. This would be increased by any constriction above the knee. There is no necessity for carrying the extension above the knee. Three shorter strips are then put around the limb, one just below the knee, one about the middle of the leg, and the other just above the ankle. Then over these plasters an ordinary roller is carried by spiral reverses of the lower extremity. The ends of the long strips that project above the knee are now turned over and secured by further turns of the bandage. A cord passes through a hole in the foot piece and over a pulley at the foot of the bed; to this a weight is fastened, by means of which continuous extension can be kept up. This is a very old mode of treatment. It was used by an eminent French surgeon, Gui de Chauliac, several hundred years ago, but this use of extension was forgotten, although it continued to be used in the treatment of joint diseases. Brodie used it for this purpose. The late Dr. Gurdon Buck revived its use in the treatment of fracture of the femur; and the method is now generally known as Buck's, or the American treatment.

The weight applied should not, as a rule, exceed twelve pounds. We have applied here one brick, which is estimated to weigh four or four and a half pounds. This afternoon we shall probably add another brick, and in the course of a week, a third. Some surgeons employ as much as twenty, thirty, or even forty pounds. I do not believe that there is any advantage in using such heavy weights; indeed, there may be harm in so doing. They might possibly, draw the ends of the bones asunder and so interfere with the union.

Besides extension, we need some support for the sides of the limb. Dr. Buck employed short splints around the limb. Others employed sand bags. I think that in fracture of the shaft of the femur you will obtain better results from the steady extension and the use of these old fashioned long splints. They are the same as were used by our predecessors without extension. These splints are from Physic's modification of Desault's apparatus. The outer splint should reach from the axilla to below the foot, and the inner from the groin to below the foot. They may be padded with cotton, a folded blanket, or, as we find convenient here, first wrapping the splints in a splint cloth, and then interposing between the splints and the limb, junk bags, *i. e.*, bags containing bran. In wrapping the splints in the splint cloth, you must be careful to allow for the difference in width of the two ends of the splint.

We now secure the splints to the limb by means of strips of bandage. Five are usually required; one at the ankle, one at the knee, one below the groin, one around the pelvis at the crest of the ilium, and one around the chest.

When the effusion into the knee joint goes down a little, and we can handle the joint without causing pain, we shall, at each dressing, if necessary, rotate the knee inward, in order to overcome the tendency to eversion. You see that by this dressing we fix the joints on both sides of the fracture. You may lay it down as a rule, that in all fractures of the long bones you must fix both the joint above and the one below the seat of fracture.

This dressing seems a little complicated when applied for the first time; but it is very simple, and requires but little attention after it has been adjusted, and it gives, I think, more satisfactory results than any other mode of treatment. The extension should be made in the line of the limb, and the leg should be in a state of slight abduction. When the patient has been removed to the ward, we shall make counter-extension, by elevating the foot of the bed.

The time required for healing is usually about eight weeks. After six or seven weeks, some form of fixed dressing, as plaster-of Paris or pasteboard splints, may be applied; but it is not safe to allow the patient to walk before eight weeks have elapsed. You may sometimes be tempted to allow the patient to go about sooner than this, and, as a result, you may have consecutive shortening. I remember a patient in the Pennsylvania Hospital who had made a good recovery from fracture of the thigh, and was allowed to go about at the end of six weeks. There was at that time one-fourth or one-half of an inch of shortening. After two or three days there was found two inches of shortening. At this time the callus uniting the bones is soft, and the pressure from walking readily causes consecutive shortening.

Fracture of Both Bones of the Forearm.

Here is another fracture case. This boy applied to the hospital and had the limb dressed yesterday. It is a fracture of both bones of the forearm, resulting from falling down a hatchway. There is a great deal of effusion and ecchymosis at the seat of injury. When both bones of the forearm are broken we should adopt means that will keep the whole limb very still; and I think it better to keep the arm in the position of supination, as has been done in this case. If the radius alone is broken, I think it better to adopt the same position. If the ulna is broken the position is not so important. If we have a fracture of the radius, particularly of its upper extremity, the upper portion of the bone is supinated by the biceps muscle, which, as you know, is not only a flexor of the arm, but also, from the position of its insertion, a supinator. If there is solution of continuity of the upper part of the radius, the upper fragment will be supinated, and unless you supinate the lower fragment you will have union with an axial deformity, and consequently, when the bone has healed, there will be loss of the power of pronation and supination.

In case of fracture of both bones of the fore-

arm, a very important part of the treatment is to use such a splint as will prevent the two bones being brought close together. To a certain extent, this object is accomplished by the position of supination. We use in these fractures a splint a little wider than the forearm, so that the pressure of the roller may not press the bones together. You must not have them too wide, or the bones may become displaced. They are to be just wide enough to prevent the bandage from pressing against the sides of the arm. We use two splints; a palmar splint, extending from the bend of the elbow beyond the fingers, and a dorsal splint, extending from just below the tip of the olecranon to the wrist. There is no occasion for a long posterior splint.

In applying these splints I place a little cotton under the upper end of the anterior splint, to prevent pain. I also place a pad of oakum in the palm of the hand. We cannot very conveniently fix the elbow joint, except by supporting the hand in a sling, which answers very well. In bandaging always leave out the thumb; this gives the patient a great deal of comfort. You see that I do not apply any roller under the splint. This is the invariable rule in all fractures of the forearm. I do not know why it is, but most of the cases of gangrene from tight bandaging occur in the forearm. I have seen one case of gangrene from this cause. A young man had a simple fracture, I believe of the radius only. A physician dressed the limb and applied a tight bandage, and did not see the case for four or five days. On removing the bandage the whole forearm was in a state of gangrene. He was then admitted to the Episcopal Hospital, with which institution I was then connected as surgeon. The arm was amputated at the shoulder joint, but the patient finally died. If you do not apply a bandage under the splints, you cannot well cause too much pressure.

In addition to the bandage I apply two or three strips of adhesive plaster, to seal the dressing and prevent it being disturbed, either by accident or by the patient. The arm is then placed in a sling and the patient instructed to keep the hand constantly supinated. The length of time required for union varies, according to the age of the patient, from four to six weeks. In this case we can probably remove the splints and have the arm carried in a sling at the end of five weeks.

Fracture of the Neck of the Femur.

Here is another case of fracture of the thigh bone; but in this instance the neck is the seat of fracture. I shall not detain you very long with this case, as I wish to perform a little operation before the close of the hour. This patient has also received a fracture of the nose, involving the ascending branch of the superior maxilla. He has also received an extensive wound of the cheek. His injuries are the result of having been struck by a locomotive. As you look at his leg you observe the same symptoms as in the other case; but one symptom is much more marked, that is, the eversion. You remember I told you that when the neck of the bone was broken the eversion was much more marked than when the shaft was broken, as the whole weight of the limb is then allowed to act in turning the leg outward.

There was no shortening when the man was admitted, yesterday; but I suspect that we shall find some to-day, because, in fractures of the neck of the femur, the shortening is usually greater some time after the injury than immediately after it. This is due to the fact that some portions of the capsular ligament which had not at first given way do so afterward, and thus allow the limb to be drawn higher up. There is barely an inch of shortening.

There was another symptom well marked in this case; that was rotation of the trochanter in a smaller arc than natural. This is a mechanical necessity in fracture of the neck of the thigh bone. There is also depression of the trochanter. This is determined by comparing the three prominences, the anterior superior spinous process, the tuber ischii, and the trochanter.

In regard to the distinctions made in the books between inter- and extra-capsular fractures, I will say that it is a very difficult matter to distinguish between them. In the majority of cases the fracture is partly within and partly without the joint. A more practical division is that which has been made by Dr. Bigelow, of Boston; that is, into impacted and unimpacted fractures; for the treatment depends upon which kind of a fracture it is. If you have an impacted fracture, the shortening cannot be very great. You understand what I mean by an impacted fracture. It is one in which the ends are crushed together, as it were; the ends of the fragments become interlocked and are held together. If you were to make forcible movements, you would get rid of the impaction: but this is just the condition you desire to maintain. You must try to preserve the impaction, because in such cases you are more apt to get bony union. In such cases you will apply no weight at all, or else very light weight.

This is not an impacted fracture. We therefore need extension. We also need a certain amount of lateral support. The fracture being so high up there is not much tendency to outward bowing. We therefore substitute for the long splints, bags filled with sand. I put a pad of oakum under the heel and then pass the extending cord over the pulley. In order to diminish the tendency to eversion, I shall carry a loop of bandage around the foot and fasten it to the inner sand bag.

The time required for union is about the same as in fracture of the shaft; that is, from six to eight weeks. When the patient is allowed to get up it is not usually necessary to use any additional dressing, because there is no risk of consecutive shortening, and not so much risk of injury as in fracture of the shaft.

Tenotomy of the Tendo-Achillis and Plantar Fascia.

This little fellow is the victim of a disease of which we see a great many cases, that is, infantile paralysis. A form of nervous disease; a disease of the spinal cord, of which you have no doubt heard from Professor Wood. One result of this disease has been contraction of certain muscles, or as the fashion is now to call the condition, contracture. We have, on the right side, the heel drawn up and the sole of the foot turned inward, a variety of club-foot known as

varus. If the heel is drawn up without inversion of the foot, the patient walking on his toes, we have talipes equinus, or horse's foot. If the deformity is in the opposite direction, the toes drawn up and the patient walking on his heel, we have talipes calcaneus. If the foot is turned outward, we have talipes valgus. Varus, the condition present in this case, is always accompanied with a certain amount of drawing up of the heel. Where the drawing up of the heel is exaggerated, the condition is termed equino varus.

What I propose to do here, is to try and straighten the foot. I shall divide the plantar fascia and the tendo-Achillis, which I think will be sufficient. I do not want to divide the tibial tendons, if I can avoid it, as in these paralytic cases tenotomy, though often necessary, must be considered a necessary evil.

I can turn the foot out pretty well, showing that there is not much contraction of the tibial tendons. I use a delicate knife or tenotome in performing this operation. In dividing the fascia, it is better to introduce the knife between the skin and the fascia, and cut downward. In dividing tendons, in most positions, it is better to pass the knife below the tendon and cut outward. I shall now divide the tendo-Achillis. Over these little punctures, I apply pieces of lint dipped in the compound tincture of benzoin and held in position by adhesive strips.

You see that now the foot can be brought into a respectable position. I now apply a flannel bandage to the leg, as it is more elastic than the ordinary bandage. Over this I apply a plaster bandage, making a few extra turns around the ankle joint. The foot will be held in this position until the plaster becomes hard, which will require about twenty minutes.

The patient will be kept in bed for a few days. In the course of a week or two we shall remove the plaster, and then I hope, by encouraging him to walk, for he still has some power in the muscles, to prevent, by the physiological use of the limb, any return of the deformity.

It may also be necessary, at some future time, to divide the ham-string tendons, but we shall do nothing further to-day.

Editorial Department.

Periscope.

Epithelioma of Leg.

In the London *Medical Times and Gazette*, Dec. 31st, 1881, Dr. Bloomfield, House Surgeon of the Devon and Exeter Hospital, reports an interesting case of epithelioma of leg in a young man—amputation below the knee—primary, and two attacks of secondary hemorrhage—subsequent recovery—under the care of Mr. Caird.

Nicholas S., aged thirty six, was admitted into the hospital in May, 1881, with an excavated and apparently spreading ulceration, commencing over the internal malleolus, and running five inches up the right leg. He is a florid and healthy-looking man.

History.—He broke the right leg in its lower third when fourteen years of age; since then he says it has been somewhat crooked and smaller than the opposite limb.

History of Present Attack.—He had always enjoyed good health, and been able to get about in his work as a farm laborer, until twelve months ago, when he first noticed a small sore breaking out without any apparent cause (there is no history of any recent injury), about two inches above the internal malleolus. The ulcer spread somewhat rapidly, getting deeper, and was attended with a good deal of pain, but his general health had not suffered. His father died at the age of forty five, six months after having an epithelial cancer removed from the lower lip.

Present Condition.—Lately this ulcer has increased rapidly in size, and he feels weaker. There is an irregularly excavated ulceration, the lower edge of which corresponds to the right internal malleolus, extending up the limb five inches. Over the internal malleolus is an elevated, bright-red-colored mass, with edges slightly hardened, and on pressure discharging little masses of a yellow color, apparently epithelial *débris*. There has been occasional hemorrhage. The edges are not raised above the surrounding skin, except over the malleolus, in which direction the disease appears to tend to spread. The deepest part of the ulcer has, as its floor, the lower third of the shaft of the tibia, which is soft and necrosed, and evidently involved in the disease. It discharges a thin, puriform fluid. The femoral glands are enlarged, but he cannot say how long he has noticed this. Small portions of the growth were cut off, hardened in spirit, and examined microscopically by Mr. Bloomfield. The examination showed the growth to be well marked epithelioma, nests being very numerous and prominent in the sections examined. He was kept in bed, put on ordinary diet, and the wound dressed with carbolic oil. He appeared to be the better for the rest in bed; his appetite was good, and he complained very little of pain in the leg. The temperature before the operation was taken on several occasions, but was never above 99°.

On June 15th, Mr. Caird amputated the leg in its upper third. The bone appeared to be quite healthy at this point. No blood was lost during the operation, and after being left open for some hours the flaps were brought together with wire sutures, and the stump exposed to the air with a small piece of gauze over it. The evening temperature was 98.8°. At 10 P.M., hemorrhage (primary) came on; pressure failed to control it, and it was necessary to remove the sutures.

Several muscular branches were tied, and the bleeding ceased; the stump, however, was left open for ten hours, and then the flaps were brought together with silk sutures tied in a bow.

June 16th.—Temperature: morning 98.4,° evening 98.8°. Doing fairly well.

18th.—Free discharge of pus. Sleeps well, and does not complain of much pain.

20th.—Slight, but sharp, attack of secondary hemorrhage from the top flap at 8.15 A.M. Evening temperature 99.2°.

21st.—Violent secondary hemorrhage at 8.30 A.M. It was necessary to apply a tourniquet above, and again take out the sutures. The bleeding did not appear to come from any large vessel in particular, but depended on a general hemorrhage from the numerous vessels in the flaps and in the bone itself. Tinct. ferri. perchlorid. was applied. The flaps appeared congested and dark colored. A consultation of the surgical staff was held to-day as to the advisability or otherwise of secondary amputation. As it appeared, however, that amputation higher up would not probably do away with his tendency to hemorrhage, and seeing that, though there had been three attacks, on the first, sixth, and seventh days after the amputation, the hemorrhage had been brought rapidly under control, so that the actual amount of blood lost in the three attacks had not been so great as to reduce him to a desperate state, it was thought best for the patient to leave the flaps open and allow the wound to heal by granulation.

The subsequent history of the case may be briefly stated as follows: The sloughs formed on the surface of the flaps by the tincture of iron gradually separated, on one occasion being attended with some considerable hemorrhage, which was checked by applying a little more of the iron. The surfaces became gradually covered over by healthy granulations, from which there was an abundant discharge of healthy pus. His general health kept up remarkably well during the trying time through which he passed. In July a special splint was applied, and the limb kept suspended. During the next two months the flaps gradually contracted by granulations, and it was possible by pressure and strapping to bring the lower flap over the face of the amputation. Toward the end of September it had completely healed over; his general health was excellent; the glandular enlargement in the groin had disappeared; and he was discharged cured on September 29th.

Remarks.—The patient was of middle height, with dark hair and blue eyes; of florid complexion, there being two bright red patches on both cheeks. Medically, after the amputation, he was treated with large doses of steel and liquid extract of ergot. From the repeated hemorrhage, it is probable that there exists a hemorrhagic diathesis. The large glandular swelling in the groin, though it eventually disappeared, suggests the probability of some secondary deposit, and this led Mr. Caird to elect to amputate below the knee, because amputation above would have been attended by greater shock to the system, which might have so reduced his strength as to hasten return of the disease in the glands. The original disease no doubt began as an epithelio-matous ulceration of the skin, and by extension involved the shaft of the tibia, which was superficially softened and ulcerated. The glandular enlargement may possibly be accounted for partly by the irritation caused by the large extent of suppurating surface; at any rate, the removal of the limb has had a beneficial effect in causing the enlargement to disappear.

Amygdalotomy and Suicide.

In a recent issue of the London *Medical Times and Gazette*, Dr. R. B. Taylor, L.R.C.P., says: In the course of an interesting and instructive clinical lecture on Amygdalotomy, delivered a short time since by the well known operator, Dr. Rubio, at the Madrid Institution for Medical Practitioners, attention was drawn by the lecturer to the frequency of suicide in young persons subsequent to excision of tonsils. Four cases of the kind, which have come under the personal notice of Dr. Ambrose Rodriguez, one of the able professors of the institution, formed the subject matter of Dr. Rubio's theme; and I hardly need say that this novel subject has aroused a considerable degree of interest in medical circles and societies.

On broaching the question of relationship between amygdalotomy and suicidal mania—a relationship which will in all probability elicit a variety of conflicting opinions and hypotheses—Professor Rubio calls attention to the immature age of the four individuals whose cases are recorded, one of whom had just completed his fourteenth year. This tender age precluding, as it does, all idea of thwarted passions, financial losses, blemished honor, *tedium vitæ*, or other etiological factors which in more advanced years commonly play so important a part in the production of suicidal mania, Dr. Rubio offers another view of the cause of this peculiar mental aberration.

The Professor's point of departure is the remarkable property which every portion of the pharyngeal isthmus, and especially the uvula, possesses, of causing reflex action in many and distant organs. The slightest touch of the uvula excites contraction of the whole digestive apparatus, from the jaws and their muscles to the pylorus, diaphragm and sphincters, creating gastric spasm and sickness. The most insignificant inflammation of the pillars or of the soft palate interferes with deglutition to a degree out of all proportion to the swelling of the affected part, just as a trivial pharyngeal angina causes violent efforts at swallowing and simultaneous overaction of all the facial muscles, not excluding even those of the eyes and eyelids.

The supposed naso-pharyngeal obstructing and voice-modulating functions of the uvula having been disproved by modern research, and no other special physiological uses having as yet been assigned to this organ, Dr. Rubio, taking into consideration the sympathetic responses of the digestive and respiratory organs to the calls of the palatal appendage, regards it as *a centre of gastric and respiratory reflex actions.* Bearing in mind the fact that *the symptoms of disease in an organ of special reflex action are transmitted to every other organ with which they are physio-*

logically connected, it is easy to account for those most diverse and apparently anomalous morbid phenomena which, due to a simple elongation of the uvula, betray their presence in larynx, lungs, stomach, heart, and head. We can, on the same grounds, explain, as Dr. Rubio has so forcibly pointed out, why certain apparently insignificant pharyngeal irritations give rise to those strange, pseudo-hypochondriacal and pseudo-hysterical groups of symptoms which, as occurring in both sexes, he has denominated pharyngeal hypochondriasis and pharyngeal hysteria.

According to Dr. Rubio, these pharyngeal reflex diseases possess features to some extent similar to those present in persons suffering from fissure of the anus. Just on the same principle as the sufferings of these latter patients induce a state of terror and mental depression bordering upon hypochondriasis, so also a fissure of the pillars of the pharynx, caused by the nipping of a portion of the same during excision of the tonsils, inducing thereby a state of incessant irritation of the unhealed pharyngeal fissure, kept up by the act of deglutition and the contact of solid and liquid food, may influence the reflex action on the brain sufficiently to lead to perversion of the affective faculties, despondence, or anger, and ultimately to self destruction.

Whatever may be the fate allotted to Dr. Rubio's ingenious theory, the relationship between amygdalotomy and suicide is, beyond doubt, a topic well worthy of careful and attentive consideration.

Drainage in Ruptured Uterus.

We learn from the London *Medical Times and Gazette* that two cases in which this usually fatal accident was successfully treated by drainage, are reported in a recent number of the *Centralblatt für Gynäkologie* (1880, No. 26). One is reported by Dr. Morsbach. The patient was aged thirty-five, and had had four children, the last five years previously. Labor came on at full term. When vigorous pains had lasted five hours, the midwife ruptured the membranes. After this the patient, who had till then been standing, felt herself obliged to lie down, and the pains ceased. Three powders, obtained from a chemist, were given to bring on pains, without effect. Ten hours after the rupture of the membranes Dr. Morsbach saw the patient. The os uteri was about eight centimeters in diameter, and the feet could be felt presenting, but high up. A dose of ergot was given, without effect. The patient was then narcotized, and it was discovered that there was a rupture of the vagina and cervix uteri, and that the child was in the abdominal cavity, except one foot, which was within the uterus. The foot was seized and the rent carefully enlarged by numerous small incisions with scissors, till it would allow the child to be extracted. The hand was then inserted, and the placenta, which was in the peritoneal cavity, was removed. Two thick caoutchouc drainage tubes were put into the rent, and a pad of salicyl wool between the thighs. Slight pyrexia followed, lasting a little more than a week, with abdominal tenderness and tympanites. One drainage tube was removed the next day, and the other on the fourth day. The patient got up on the fourteenth day. Fourteen weeks afterward she thought herself quite well. There was then a deep fissure in the cervix posteriorly, the bottom of which could not be reached by the finger, and a cicatrix in the posterior vaginal wall. Dr. Morsbach thought it possible that the midwife may have ruptured the uterus when she thought she was only rupturing the membranes, for she admitted that she had found great difficulty in doing what she did. The other case occurred in Berlin, and is reported by Dr. M. Graefe. The patient was in labor with her thirteenth child. The pains continued for six hours and then suddenly ceased. An hour afterwards she was found in a state of collapse, the face presenting, an arm down in front and a foot behind. Incomplete rupture of the uterus was diagnosed, and the patient was removed to the hospital. When she got there it was plain that the child was in the abdominal cavity, the contracted uterus being felt in front and to the left of it. The hand was introduced, a foot seized, and the child extracted; then the placenta was removed. The uterus was found ruptured transverely, only about three fingers' breadth of its wall remaining entire. The peritoneal cavity contained much clotted blood and meconium. It was washed out with a 2½ per cent. carbolic acid solution, and then a thick drainage tube, thirty centimeters long, put into the abdominal cavity and secured by a silk suture to the posterior commissure. A bandage was put round the abdomen, and on it an ice bladder. During the first two days the pulse was hardly perceptible. Hiccough and vomiting were troublesome during the first five days. The temperature did not rise till after the sixth day, when she began to have evening exacerbations of fever, which continued until the beginning of the fourth week, after which the temperature remained normal. After the sixth day the parts were irrigated from one to three times daily, through the tube, with a 2½ per cent. solution of carbolic acid. The tube was removed on the thirtieth day. The patient left, well, on the thirty-fifth day.

Frothing Urine and its Causes.

Dr. Kirk has an excellent study on this subject in the Glasgow *Medical Journal*, for October. He says:—

My observations have been chiefly confined to the urine, and especially to albuminous urine. It is evident that the spontaneous production of froth or air bubbles on the surface of any urine must depend on two causes: (1) a certain property of the liquid, and (2) the presence of gas in it. If any gas arise from decomposition, or air be introduced by agitation, these bubbles will form in proportion as the liquid possesses the property which gives rise to them. What class of urines most readily produce gases, or to what extent the production of such gases is to be regarded as pathological, I have not made the subject of observation; my attention has been solely directed to the degree in which various urines possess the property which enables these bubbles to form when a current of air of given amount is driven through them. Proceeding in this way I obtained the following results:—

1. Urine, whether normal or otherwise, is almost invariably frothy, so as to be easily distinguished from mere water by this peculiarity. This, indeed, any one may observe in the act of micturition.

2. The degree in which urine possesses the property on which this phenomena depends varies extremely in different cases, but it is never very great except in pathological urines. I have found it highest in—1. The majority of specimens of albuminous urine, but certainly *not in all.* 2. Certain high colored urines. 3. Some urines containing bile pigments, although in such cases it was not much above normal.

It was evident that the power of frothing depended on certain constituents, and the proportions in which they might be present. These constituents seemed to be, in healthy urine, the extractives (more especially, perhaps, creatinine). Not all the pigments, however, seemed to confer this property on the urine, for I have met with one specimen of a very high colored urine which gave scarcely any froth with the air current.

With regard to the plasticity of the fluid, he found:—

1. Serum albumen (equal quantities, as nearly as could be estimated, being compared) has greater plasticity than ovalbumen.

2. Fibrinogen, from hydrocele serum, and fibrinoplastin (serum globulin), from blood serum, have a high degree of plasticity, but I could not venture to say whether it is greater than that of serum albumen.

3. When albumen is transformed into acid or alkali albumen, or when the salt is removed from it by dialysis, the plasticity is at first not much affected, but in these cases it is sooner lost by keeping than otherwise.

4. When salt is added to an albuminous liquid the plasticity remains a long time. It also counteracts the effect of acid or alkali on the plasticity.

5. Any agent (as salt) which preserves the plasticity, also preserves the albumen longest from decomposition; or conversely.

True Ozæna.

M. Calmettes, in a recent number of *Le Progrès Médical* (October 8th), has made a critical study of the works and theories on the above subject. The study of this affection has entered on a new phase, through the labors of Zaufal, Michel, Hartmann, and Gottstein. The thesis of M. Martin, a memoir giving the result of two autopsies by Hermann Krause, and a large work by Cozzolino, giving a résumé of all the different opinions on the subject, are the latest additions to the literature of this disease.

The epithet "true ozæna" is used to distinguish this disease from those cases of simple nasal catarrh in which the mucus collected in the nostrils is in the morning somewhat fetid. Some cases of ozæna with notable fetidity are due to bone lesions, either syphilitic or traumatic. But in the great majority of cases, diathesic antecedents and bone lesions cannot be demonstrated, and such cases present such a uniformity of symptoms as to suggest the existence of one causation in all. They are generally observed at the period of puberty, and when met with in adults it will be found that the troubles date from this period of life. Many explanations and theories concerning this affection were put forward before rhinoscopy was currently practiced. Sauvage, and recently Dr. Tillot, believed that in such cases there existed a stricture of the nasal fossæ, which caused the retention and subsequent decomposition of the nasal secretions. Trousseau, who had remarked that children suffering from this affection often enjoyed flourishing health, admitted a special fetidity of the secretions analogous to bromhydrosis. But, unfortunately for the patients, the general opinion was that ulceration existed, and caustics were employed, with or without irrigations.

The patients say that the nasal secretions are not liquid; that every second or third day they with difficulty expel from the nostrils large masses of hardened, greenish mucosities, of exceedingly fetid odor. They suffer from cephalalgia, and sleep sometimes with the mouth open the night preceding the expulsion of these masses. Generally there is no sign of scrofula, no anterior nasal affection, and rarely auricular complications, according to Michel, contrary to the opinion of Zaufal. The anatomical peculiarity in these cases has been shown by Zaufal to consist in the great width of the nasal fossæ, due to an exceedingly small lower turbinated bone, which can sometimes with great difficulty be distinguished; the middle turbinated bone is often of normal dimensions, and the mucous membrane which covers it is smooth, red, and sometimes granular, but without any trace of ulceration; this is demonstrated in the five autopsies of true ozæna which have been published. Before the nose is irrigated there is such an abundance of crusts in the nostrils that their abnormal width is not evident, and there seems to exist a number of grayish ulcerations.

In accordance with the anatomical abnormalities found, Zaufal considers that the disease is due to the extreme width of the nasal fossæ, which permits the stagnation of mucosities and their decomposition, as they are constantly exposed to a current of hot and humid air; this renders the secretion fetid. Michel considers that this is not sufficient to explain the extreme fetidity, and considers the sphenoidal and ethmoidal tissues must be affected. Gottstein holds that histological investigation proves the existence of a catarrhal state of the mucous membrane, with atrophy and partial disappearance of its glands. These theories, with the exception of that of Zaufal, which seems the best founded, are not in concordance with symptoms observed in the majority of cases. The treatment indicated by the nature of the disease gives excellent results. After a few irrigations with a solution of chlorate of potash, Gottstein advises a tampon of cotton wool to be placed in one of the nasal fossæ; this tampon, occupying the place of the absent inferior turbinated bone, narrows the nostril sufficiently to enable the patient to expel the mucous secretions in a liquid form, before they have acquired any odor. The tampon, soon covered with adherent mucosities, is expelled spontaneously on the second or third day. The effect of this measure is so assured that it is not

absolutely necessary to remove the dried crusts by preliminary irrigation. Gottstein is of opinion that this application irritates slightly the atrophied mucous membrane and induces a more normal secretion; but this explanation appears, to say the least, insufficient, as the tampon is applied on one side only. This treatment seems to prove very effectual, and is even used by M. Fournier, who considers the disease due to a fetid secretion (exhalaison) from the glands of the nasal mucous membrane.

Two Cases of Peritonitis Apparently Due to Diphtheria.

Dr. William C. Dabney, of Charlottesville, Va., writes to the *American Journal of Medical Sciences*, for October, 1881:—

In the months of December and January last there occurred in a large female school in this vicinity an epidemic of measles. The cases were, I learned from the attending physician, Dr. Bowcock, generally mild, and all, so far as I know, terminated in recovery.

Following on the heels of the measles there occurred an outbreak of diphtheria, which, with the exception of two cases, was so mild in character that the disease was not at first recognized, and Dr. Bowcock was not called in.

No cause could be found for the outbreak. It may safely be affirmed that no institution in the country is better managed, and nowhere is more attention paid to the hygienic surroundings of the pupils.

Case 1.—About the 10th of January, Miss M., one of the teachers, about 26 years old, was taken with quite a severe sore throat, but as there was no diphtheria, so far as known, in this section at the time, no apprehension was felt. She was much better in a few days, and about the 15th her monthly sickness came on. This ceased on the 20th, and on the 22d she came to Charlottsville, a distance of six miles, on the train, and was very busy all day. She returned on the afternoon train, much fatigued, and when she reached home she complained of "cramps" in her abdomen, but ate a hearty supper. In the night she suffered so much that she took some laudanum, and the next morning was well enough to be at breakfast.

During the day of the 23d she complained a good deal of pain, but Dr. Bowcock did not see her till the 24th, when he found her with considerable fever, marked tenderness in the lower part of the abdomen, a quick and rather weak pulse, and great nausea. Appropriate remedies were administered, and that night she seemed better, but the following day, January 25th, he found her with an extremely weak pulse and in a state of collapse. I saw her, at Dr. Bowcock's request, about 3 o'clock on the afternoon of the 25th, and found her in a state of extreme prostration, pulse almost imperceptible; there was great restlessness and tenderness over the whole abdomen. She sank rapidly and died at 5 o'clock the same evening, consciousne s being preserved almost to the last.

We were strongly inclined to attribute the peritonitis in this case to diphtheria, though neither of us had seen or heard of such a case before, nor had Dr. J. S. Davis, of the University of Virginia, who was kind enough to come to our assistance, but who reached the house only a little while before the young lady's death.

Case 2.—On the 5th of February following, I was called by Dr. Bowcock to see Miss O., one of the pupils in the school. She was suffering with diphtheria, and there was marked tenderness and pain in the abdomen, especially about the lower part. Her pulse was very feeble, and her temperature high (I cannot recall the exact figure). Full doses of opium were administered and hot applications made to the abdomen.

Dr. Davis was kind enough to see this case with us the next day, and he agreed with us in the diagnosis, and gave, as we had done, an unfavorable prognosis. She threw up, on the 6th, a good deal of false membrane, and we were informed by one of those in attendance on her that she had passed membrane by the bowels also. The case ran a very similar course to the previous one, and the young lady died on February 7th.

The occurrence of peritonitis as a sequel or complication of diphtheria seems to be extremely rare, if we may judge from the fact that it is alluded to by very few writers on the subject.

High Local Temperatures.

Dr. William Squire contributes the following interesting information to the London *Lancet*:—

A long attention to surface thermometry, while revealing numerous sources of error, such as undue or unequal warming or covering of the part to be examined, shows some very real and important differences; these deserve careful note, and will some day admit of useful generalizations. As a provisional deduction, it may be stated that these natural variations seldom exceed by as much as 4° or 5° that of a corresponding part of the surface, and are still more rarely even a degree above the internal or general temperature of the body. How largely the reverse of this may be possible is well known. Collapse may set in from an intense fever at its height, and the limbs be algide while the head and body burn. During scarlet fever the temperature *in recto* has been 105°; and at the same time only 97° in the skin of the abdomen or in its folds. In the axilla an accurate surface thermometer has marked 103° on the thoracic side and only 98° on its brachial aspect; this was found in acute pulmonary congestion near the close of chronic lung disease. In right hemiplegia of two months' standing the paralyzed arm and the left side of the face were two and three degrees higher than the parts unaffected; the surface temperature of the head over the side corresponding to the supposed seat of cerebral lesion being 1½° lower than the opposite side. From some obscure affection of the cervical sympathetic, probably, an active man thirty years old has a persistent flush on the left side of the face. This is worse when he is heated; on any little exertion or excitement that side of the face and forehead are bedewed with perspiration; the temperature, while he is at rest in a cool room, is 4° higher on the left temple than on the right; it was 90° on the right and 94° on the left temple

in the morning of a cold day. A difference of a half a degree is frequently found on the two sides of the forehead. The range in health at various times of the day and under varying conditions is usually from 92° to 96°, but the difference between the two sides is seldom as much as half a degree, and the left temple is rather more often the higher than the right. There are some conditions of hemi anæsthesia and hyperæsthesia where the symptoms more or less suddenly change from side to side, that have a like curious variation in temperature. These cases have a variation of only two or three degrees, and are not limited to hysterical subjects. A temperate man near the age of forty had to lay up for three weeks, for pyelitis and renal irritation, with severe headache, chiefly on the left side; in early convalescence, with normal temperature *in ore* the right temple was 96.4°, the left 94°, and it was noted as curious that the temperature of the right axilla was only 97.6°, while the left was 98.2°. The following week, during a relapse, the temperature at noon *in ore* was 100.6°, that of the right axilla 101.6°, of the left 100.3, both temples close on 98°. At night the general temperature was 101°. His temperature on the next day at noon was 98.6° *in ore*, 98.8° *in recto*, right axilla 98.2°, left 97.4°, right temple 94°, left temple 94.5°. Urine pale, sp. gr. 1.016, slightly turbid, mucous deposit, a trace of albumen. Pulse 80, respiration 18. Before recovery was complete headaches with loss of sleep recurred, with shifting of the increase of temperature from the right axilla and right side of the trunk to the left side, and of the higher head temperature from the left to the right, and *vice versâ*, more than once.

Bromine Topically in Chancroids and Chronic Ulcers.

Dr. J. L. Robinson, of Louisville, Kentucky, writes, in the *American Practitioner*, for November, 1881:—

Within the past few months I have had opportunity of testing bromine as a local application to chancroids and chronic ulcers, associated with syphilis, as seen in the United States Marine Hospital in this city. The following is the formula used:—

℞. Bromine, one part; water, three parts; bromide of potash, q. s. to make a solution. To be applied once daily by means of a mop made of cotton wool.

I subjoin a very brief report of a few of the cases treated:—

Case 1.—W. C., colored, chronic ulcer of two years' standing over the anterior middle third of the tibia. First seen April 1st, when the granulations were large, flabby, and raised, and the surrounding tissues excessively indurated. Applications of nitrate of silver and sulphate of copper were used daily for nearly a month without effecting any change in the character of the sore. May 1st, I applied the bromine solution and continued it daily. Each application was followed by oakum to the sore and a flannel roller to the limb. In two weeks the granulations came to a level with the surface and were of healthy aspect, the surrounding integuments grew soft and pliant, and cicatrization set in. Some weeks after the ulcer was reduced half its former size, and healed rapidly.

Case 2.—C. H., colored, admitted June 30th, having a large ulcer of six months' standing, situated as in Case 1, and altogether of similar character. The bromine, oakum, and the roller were at once applied. Improvement was noticeable from the first day, and speedy cure seems assured.

Case 3.—S. H., white, admitted July 12th, with an ulcer of both legs, just above the internal malleoli. Much the same appearance as in cases just described. The same treatment effected almost at once the most striking change, and in four weeks the patient was discharged cured.

Case 4.—A. L., colored, admitted July 2d, ulcer four square inches in size, of six months' standing, situated just above the ankle on the inner side of the right leg, cup-shaped, covered with a greenish slough, and made offensive by a fetid, ichorous discharge. The bromine, etc. quickly reduced the ulcer two thirds in size, besides converting it in all respects into a healthy sore, which gives promise of uninterrupted and quick cure.

Case 5.—J. L., white, admitted August 2d, with a large. indolent ulcer of two years' standing immediately above the external malleolus of right leg. Numerous smaller ulcers existed in the region of both ankles. Bromine, oakum, and the flannel roller accomplished much the same results as in the previous cases.

Fifteen grain doses of the iodide of potassium, given three times daily, made up the constitutional treatment in the foregoing cases, except in Case 1, where cod-liver oil was deemed advisable.

I have also used the bromine in several cases where, after the operation of circumcision, inoculation of the entire raw surface had occurred, with equally good, I might even say with better results than in the leg ulcers.

Alcohol in Therapeutics.

In a communication on this subject, to the *Medical Record*, Dr. Lewis D. Mason, of Fort Hamilton, N. Y., says that the medical officers of the Inebriates' Home, at Fort Hamilton, have, within the past two years, adopted the plan suggested by Dr. Benjamin W. Richardson, of prescribing pure alcohol instead of wine, beer, or whisky, whenever, in the treatment of various forms of alcoholism, the use of alcohol was indicated, and have found the following benefits to proceed therefrom:—

1st. The satisfaction of having a solution containing a definite percentage of alcohol, thus providing an exact system of dosage.

2d. A very marked saving, and therefore, a method of value from an economical point alone, especially in those institutions where the liquor bill is a large item of expense.

3d. The moral effect on the patient, in compelling him to at once break off his accustomed stimulant, and providing a "medicine" as an efficient substitute.

4th. The advantage which the alcohol has over brandy, whisky, etc., is that, owing to accuracy and concentration of the dosage, the patient convalesces in one-half the time and with less suffering.

Another advantage which this method of prescribing alcohol possesses is the lesson which the community will receive, in a quiet way, that the proper place for alcohol in any of its forms or combinations is the shelf of the pharmacist.

Moreover. in a properly compounded prescription containing alcohol, the physician will have a much greater control of the future physical and moral welfare of his patient, than if he directed him simply to take alcohol as contained in one of the various forms of liquor in common use. The alcohol should always be disguised by the addition of the various carminatives or bitter tonics, and also colored by caramel, so that the patient may not be unnecessarily informed as to what he is taking.

Hemorrhage due to Foreign Growth.

Dr. W. H. Lewis, of Graysonville, Mo , sends the following report of a case to the Louisville *Medical Journal*, for December, 1881:—

About a week ago I was called in haste to see Mrs. B., who had been suffering for several days from what she took to be painful menstruation. I found patient looking very pale and flooding profusely. Her clothing and the bedding were saturated with blood. I called for warm water, and while waiting for it, I removed the pillows from her head and elevated her hips instead. On making a digital examination I found the os dilated and bright arterial blood flowing from the uterus. Cold cloths were applied to the abdomen and warm water injected every half hour. Soon the hemorrhage was under comparative control. I also gave several large doses of fluid extract of ergot and stimulants freely.

As she still continued to have considerable hemorrhage, I made repeated efforts to introduce my hand into the uterus, and succeeded in introducing two fingers, when I found attached to the uterine walls a fleshy lump about the size of a hen's egg. After repeated efforts I succeeded in detaching this and removing it, when the hemorrhage ceased entirely and did not return. Under tonics and liberal nourishment she is now doing well.

Infectiousness of Blood and Urine of Tuberculous Animals.

The Glasgow *Medical Journal* for January, 1882, makes the following interesting report of some experiments on this subject, by V. Lentz, of Griefswald:—

In six rabbits he injected fresh blood of tuberculous rabbits into the lungs through a tracheotomy incision. In all of these, killed in from 92 to 216 days afterwards, he found miliary tubercles in the lungs, and in four of them in the liver as well. In one he found caseous masses in the lungs.

In all of four in which the blood was injected subcutaneously (killed after from 125 to 148 days) he found miliary tubercles in the lungs, and in two of them in the liver as well.

In one the blood was injected into the joint and adjoining connective tissue. The knee became swollen by the third day; on the 18th the animal died, and dissection showed stinking caseous suppuration in the joint, and tubercles in the lungs.

Two rabbits were subjected daily, for 71 days, to an atmosphere charged with steam containing from 30 to 40 ccm. of freshly voided urine from tuberculous animals. After death the lungs were found full of minute sub-pleural ecchymoses and numerous peri-bronchial tubercles.

With three others "phthisical urine, which had been allowed to stand for several days in a warm room, was used. One died on the ninth day, after aborting, and examination showed in the peri-bronchial connective tissues numerous masses of round, well defined nucleated cells, "undoubtedly commencing tubercles." In the others (killed on the 48th and 60th days), tubercles, less numerous, but more uniform in nature and position than in the rabbit treated with fresh urine, were found.

In all the sections of tissue examined, a decided thickening of the arterial coats was observed.

Joints from a Case of Gout.

At a recent meeting of the Pathological Society of London, Dr. Norman Moore showed the knee, larynx, kidneys, and brain of a man who died a few hours after admission into hospital. The patient had had repeated attacks of gout. A deposit of urate of soda was found in various joints, but not in the vertebral joints; the amount of deposit in the knee joints was very remarkable; and in the right knee joint a quantity of purulent fluid was found. The kidneys were in an advanced stage of interstitial nephritis. On the left side of the cerebellar hemisphere there was a white plate in the pia mater. This plate contained a trace of uric acid. The bony tissue of the tibia contained no uric acid. No trace of lead could be found in the liver; lead, Dr. Moore observed, probably merely tended to produce gout by checking excretion, and not by any more direct action. Dr. Dyce Duckworth observed that the relation between gout and lead poisoning was a very certain and very interesting one. He thought this an interesting case, inasmuch as it was clearly shown that suppuration had occurred in one knee joint. This was a very rare condition; in some of the other cases on record the patients had suffered from erysipelas; but in this case there was no history of erysipelas, and therefore it might be regarded as a true case of suppuration in a gouty joint. Dr. Curnow said that two years ago he had examined a body in which nearly every joint of the lower limbs contained urate of soda; but in this case there was no suppuration. The vertebral joints and the joints of the upper limbs escaped. He thought that any suppuration which occurred in gouty joints was an accidental complication.

Medicine in Japan.

According to a recent return, Japan possesses 159 hospitals, in which the patients are treated on principles recognized by Western nations. Vaccination is performed gratuitously, and is compulsory. Moreover, a sort of Medical Act has been lately passed, by which persons without certificates are prohibited from practicing medicine or surgery.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

STEAMER SURGEONS.

The English journals are just now discussing the position of surgeons on steamships and sailing vessels. It seems that their position is, indeed, a very anomalous one. They are poorly paid, their authority is very limited, and their duties ill defined. This is, in reality, a much more serious question than would at first thought appear. Americans, as great travelers, are much interested in this subject, and a few thoughts pertaining to it will, indeed, be of interest and importance to them.

What sensible person would take up his residence in any locality without first inquiring whether a competent physician was near at hand. It would be, justly, a very essential consideration. How is it on the ocean steamers, plying between America and Europe? The surgeon of a trans-Atlantic steamship is usually regarded as a very ordinary physician. Why? Because the pay is so little that it is impossible for the companies to secure the services of gentlemen whose acquirements are sufficient to procure them lucrative practice on shore. What are the results of this state of affairs? Few tourists stop to realize them. A man takes his family on board a steamship bound for Liverpool, and no matter what medical emergencies may arise, no matter how sick any of them may become, for the space of ten days or two weeks the only medical attendance they can possibly receive is that furnished by the ship's surgeon. If he be competent, so much the better; if he be not, then the poor patients *must* suffer the consequences, since it is utterly impossible for them to change doctors, unless, perchance (which rarely occurs in proportion to the number of trans-Atlantic voyagers), some capable physician happens to be among the passengers.

Suppose on a stormy day, one of the passengers falls on deck, or is thrown down stairs and breaks his leg; and suppose the physician of the ship is not a good surgeon; life deformity may result. Suppose a man has hernia, and during the voyage it becomes strangulated; if a good surgeon is not at hand, he must die. We could suppose a hundred surgical emergencies that might and do arise during an ocean voyage, requiring immediate application of accurate knowledge, with death as the alternative of lack of this familiarity with surgical science. The position of surgeon on an ocean steamer is by far the most responsible position in which a physician can be placed. When, on shore, and particularly in a large city, a physician is called to a case beyond his compass, he has a large number of medical brethren from whom to select one more competent than himself. How different at sea, when single handed and alone the ship's surgeon must be prepared to intelligently master any emergency that may arise, without one word of advice, encouragement or counsel, and without any division of responsibility. Truly, indeed, may his position become a trying one, such a one as to tax the ability of the greatest and most experienced of surgeons. How, then, can it be reasonably expected that such a responsible position can be capably filled for the paltry sum of seven or eight hundred dollars. We would

ask any of our rich and aristocratic European tourists whether they would trust the lives of their wives, their children, or themselves in the hands of a physician whose abilities were of such a calibre as to command a practice of only seven hundred dollars a year. Yet, whenever they cross the ocean, they not only do trust to such medical ability, but they do so absolutely and without the possibility of calling in one more competent.

How, then, can this state of affairs be remedied? By the establishment of a thoroughly efficient, graded merchant medical service, based upon the plan in vogue in the navy. Each steamship company should have its well paid medical superintendent, and each vessel should have *two* well paid medical men. With a salary of three thousand dollars for the surgeon, and two thousand for the assistant surgeon, such talent and experience could be secured as would render the lives of ocean voyagers reasonably secure, and would assure them of proper medical attendance.

The additional cost to the steamship lines would be comparatively small, and when viewed in the light of duty and justice to passengers, would be money well spent. The company inaugurating such a plan would find their passenger traffic more than they could accommodate, as soon as their reform became known. Such remuneration would induce capable men to apply for the positions, while an initiatory, followed by periodical examinations (uninfluenced by favoritism) would keep the service thoroughly efficient.

THE NATURE OF THE CAUSES OF DISEASE.

It is very discouraging, when we consider the great antiquity of the art of medicine, to realize how little accurate knowledge we possess of the intimate nature of the causes of disease, and how diverse are the views of eminent men on this subject, thus demonstrating by this very diversity how uncertain and untenable are the views held by each.

A remarkable illustration of this is afforded by the result of recent investigations into the nature of the specific poison capable of producing periodic fever. Tommasi-Crudelli makes some elaborate investigations and experiments, and announces to the world that he has at last discovered the true nature of this poisonous germ. Dr. Sternberg is ordered to investigate his experiments, and as a result comes out with a flat denial of the Italian's conclusions. Now who are we to believe, and what shall we accept. After many months of hard labor abroad and at home, we are left in as much doubt and know as little as we did before. Must it not be discouraging to Crudelli to have his conclusions emphatically denied, before they have hardly been made public. Still it is proper that this should be, since error must always be at once corrected.

Again, a writer treating of the Japanese disease, *Kakki*, says, "It is the opinion of those who have studied the disease that it is caused by a specific poison. Dr. D. B. Simmons, of Yokohama, whose residence of over twenty years in Japan, and familiarity with the disease in all its phases, entitle his opinion to the highest respect, believes that its cause is "*a specific miasm, or soil exhalation, like paludal malaria.*" Overcrowding, bad drainage and bad ventilation seem to develop the poison in systems debilitated by these or other causes, as sedentary occupations, labor, low diet, or non-assimilation of food; while non-acclimatization, occupation, diet, season and sex, seem to be the principal predisposing causes." Truly a comprehensive etiology, one whose very extent argues its uncertainty.

So it is with the most prevalent and most fatal diseases. Diphtheria is a remarkable illustration; smallpox, yellow fever, and cholera are the same. It may be argued that we do know the nature of the cause of these latter diseases, since we know that they are produced by contagion. But we do not understand the nature of the element which is the active agent in this contagion. We do know how to avoid smallpox, yellow fever, and cholera. We know how to escape from a malarious atmosphere, and how to alter such a locality into a harmless and healthy place of residence. Does it not seem likely that we never will be able to thoroughly understand

this minute etiology of disease. Will it not forever elude our grasp? Is there not a limit to human penetration, and is not this knowledge only to be found in the space outside of this limit? Some will say, yes; some, no. Let those who desire to so amuse themselves go on in their studies; if they ever reach any definite conclusions, which we doubt while we pray for, the world will be greatly benefited by their studies.

In the meantime the majority of physicians should be practically utilizing that prophylactic knowledge which we do possess. It should be their first duty to warn their neighbors against the causes of disease existing in their vicinity; and their second duty to endeavor to cure such disease, when contracted in spite of their caution. An ounce of prevention is worth many pounds of cure, and it becomes the conscientious duty of every respectable physician to utilize this preventive power.

Notes and Comments.

Post-mortem Contagiousness of Diphtheria.

Dr. G. S. Gerrard writes to the London *Lancet*, detailing a case which tends to substantiate the idea that a person may catch diphtheria from one dead of the disease. Two young persons were engaged to be married. The man was seized with diphtheria and died. The body was removed, for interment, to the town in which the girl lived. The coffin was opened, and no doubt the girl kissed her lover. Three days afterward she was seized with diphtheria. There were no other cases in the vicinity, neither had a severe case been known there for nineteen years, and its production could only be traced to contagion from the dead body. This circumstance gives us a hint as to the handling of those dead from this disease.

Transient Mania from a Bed-Bug in the Ear.

Dr. A. B. Kibbe reports, in the *Rocky Mountain Medical Times*, a curious case which well illustrates the power of imagination. He was consulted by a woman, sixty three years of age, who said she had been awakened early in the morning by a bed-bug crawling into her ear. Examination revealed a minute black speck directly in the centre of the membrana tympani. The ear was filled with glycerine, and upon subsequent inspection the object had disappeared, and she felt much better. A pellet of cotton was placed in the ear. Four hours later he was called to see her, being told that she was "crazy." She was found crouching in a corner, almost nude, screaming and beating the floor with her hands. In about an hour she became quiet enough to say that she had pushed the pellet of cotton into her head, and begged for its removal. An examination afforded an unobstructed view of the drumhead. A friend slipped a small wad of cotton into his hand as he withdrew the speculum. Upon seeing the cotton (the supposed presence of which in her head had been the cause of her mania), she experienced immediate and complete relief.

Treatment of Acute Articular Rheumatism.

We read in the *Concours Médical* (*No.* 48), that Dr. Carpani, having made numerous observations, and studied the best authorities on the subject, has divided the different methods of treating this affection into the following four groups, each with special indications:—

1st. Salicylate of soda is useful in cases of acute febrile polyarthritis, attended by highly localized articular manifestations. It is contra-indicated by the concomitance of cardiac affections, nervous troubles, or gastro-intestinal or renal difficulties.

2d. Bisulphate of quinine is indicated in cases where rheumatism is a manifestation of, or associated with, malarial infection.

3d. Benzoic acid should only be used when nephritis is a complication of acute articular rheumatism, attended by fevers.

4th. Blisters (Dechilli's and Davies' method) are the most reliable agents for curing mono-articular rheumatism, or that form in which but few articulations are interested.

Papaïne in Diphtheritic Conjunctivitis.

Messrs. Bouchut and Hubert have lately met with quite a number of cases of diphtheritic conjunctivitis in the Hôpital des Enfants Malades. They have treated this hitherto somewhat rare disease with applications of papaïne dissolved in distilled water:—

℞. Papaïne, 2 grams = (ʒ ss).
Distilled water, 8 " = (fʒ ij). M.

and the children have all been cured. Quite lately another child suffering from this species of diphtheritis was similarly treated and recovered in three days' time.

Intestinal Invagination.

The *Concours Médical* reports a case of intestinal invagination, observed by Dr. Grosoli, which terminated in a very surprising manner.

A child, ten years old, had eaten oranges and lemons, swallowing skin and seeds, as is often done in the south of France. He was taken with violent pains, and vomiting soon set in. Castor oil, and other purgatives, injections, leeches, hypodermics of atropine and morphine, hot and cold applications, electricity, all were without effect. The symptoms grew daily more serious; vomiting became fetid and stercoraceous, and the abdomen extremely painful to the touch. The little patient had thus laid for twelve days, agonizing, and only sustained by nutrient injections, when Dr. Grosoli conceived the idea of administering 30 grams = (ʒ viiss) of mercury. Two hours after this had been taken there was an expulsion of gases and fæces mixed with blood and mercury. This passage brought on some relief, but the pains only ceased on the evacuation of a membrane having a strong gangrenous smell. On the following day the patient passed a piece of the lesser intestines 40 centimeters = (15.7 inches) long, and for a period of fourteen days he continued having slight pains in the abdomen, and at intervals passing fragments of intestine. The case progressed most satisfactorily, and at the end of a month the child was entirely cured.

Bacteria as a Cause of Leprosy.

From the London *Medical Times and Gazette*, we note that Dr. Cornil arrives at the following conclusions concerning the seat of bacteria in leprosy and the lesions of organs in this disease. The tissues which he examined were so filled with bacteria, and so modified, that it was difficult even to determine what organ he was dealing with. The lesions in their direct relation to the bacteria were divisible into two series.

1. The leprous tubercles and infiltrations are characterized by large cells in colossal numbers, which infiltrate the diseased tissues and are filled with minute bacteria. When the leprous infiltration attacks a soft organ, like the liver, or one possessing natural cavities, like the testes, the bacteria become very voluminous. 2. In most of the fibrous tissues the bacteria throw out long filaments in the interstices of the fibres, the fixed cells of the fibrous tissue being little changed or normal. Sclerosis or thickening of the fibrous tissue, however, often resulting in leprosy. The disease seems, beyond doubt, to be caused by the bacteria.

Curious Case of Aneurism.

Dr. J. A. Temple reports a singular case of popliteal aneurism, in the Canada *Lancet* for January, 1882. The aneurism was first treated by digital compression, which was persistently maintained for thirty-two hours, at the end of which time both pulsation and bruit had disappeared, and remained absent for four days. Gradually, however, they both returned, with swelling, which extended upward on the thigh. Operative interference was refused, gangrene supervened, and the patient died. The post-mortem revealed a spiculated outgrowth of bone from the posterior and upper part of the inner condyle of the femur, measuring one and a half inches in length, and terminating in a sharp point. This point had penetrated the sac, and was, most likely, the primary cause of the aneurism, by injuring the coats of the artery. The patient was only twenty four years old.

Smallpox and the Paper Makers.

The *Sanitary Engineer* says: Among the many modes of spread of smallpox, that by means of rags merits special attention. That the danger is by no means an imaginary one, is shown by the experience of Holyoke, where several cases of, and deaths from, this disease have occurred. That all rags should be thoroughly disinfected by heat, chlorine or sulphurous acid gas, or by a combination of these methods, before they are given to the sorters, and that all employés in paper mills should be vaccinated, are simple common sense suggestions which should commend themselves to the owners and managers of such establishments, and which health authorities should use their influence to secure.

Physicians living in the neighborhood of mills should make it their duty to call the attention of manufacturers to this danger.

Antiseptic Properties of Essence of Wintergreen.

We see in the *Concours Médical*, that Professor Gosselin and Dr. Bergeron have experimented with oil or essence of gaultheria (*gaultheria procumbens*), wintergreen, and have obtained good results from it, as an antiseptic in the dressing of sores.

Essence of wintergreen is much used in perfumery; it has an agreeable odor, and is insoluble in water, but soluble in alcohol.

Two solutions are used by Prof. Gosselin:—

No. 1.	Oil gaultheria,	fʒ i¼
	Alcohol 60°,	fʒ xiiss
and No. 2.	Oil gaultheria,	fʒ ⅝
	Alcohol,	fʒ iij–fʒ j
	Water,	fʒ xiis

Special Reports.

No. III—INFECTIOUS DISEASES.

So much additional light has recently been thrown upon the nature and treatment of contagious or infectious diseases, that a special report on this subject will be interesting. It is in the field of medicine to which infectious diseases belong that we must necessarily look for the greatest strides in preventive medicine. When we succeed (if we ever do) in acquiring an intimate acquaintance with the active causative agent of these diseases, and when we know how to render abortive and powerless this agent or these agencies, then, indeed, will preventive medicine rank, as it justly should and surely will, as the highest branch of our great science. Many great men are now actively engaged in endeavoring to unravel the mystery of causation, and much good work has been done in this direction, which gives abundant promise that great success will crown their efforts in the future. Among these earnest laborers in this interesting field we may make mention of such well known names as Pasteur, Touissant, Koch, Klebs, Tommasi-Crudelli, and Lister, in the Old, with those of Sternberg and Wood, in the New World. Such names guarantee earnest and conscientious work, and are full of promise of success.

We will take up the principal contagious diseases in order (commencing with diphtheria), and will concisely state the most recent views and facts concerning their etiology, pathology, diagnosis and treatment. Smallpox will be treated in a separate report.

Diphtheria.

Its Etiology.—In his "Practice of Medicine," published in 1868, Flint seems to have very vague and indefinite ideas concerning the causation of diphtheria, as evidenced by the fact that his remarks on its etiology are confined to asking the question, "Is the special cause a contagious virus or an infectious miasm?" After which, for a few lines only, he discusses the question of its contagiousness or communicability, and concludes by regarding the question as *sub judice.*

Since that period much labor and time have been expended in endeavoring to penetrate the mysterious cause of this disease, and while we do not yet certainly know its nature, still we have made progress, and know more to-day than he did then.

As far back as 1858, Professor Laycock, of Edinburgh, advanced the theory, in the London *Lancet*, that the exudation of diphtheria was due to the *oïdium albicans*, or potato fungus, in support of which theory it was stated that Gruby, of Paris, in 1844, had shown by the microscope that in pseudo-diphtheria, or muguet, and in thrush, the buccal pellicles displayed the tubular filaments and mycelium of a vegetable form analagous to oïdium. At the time, this theory was not generally accepted, since the microscope failed to furnish sufficient evidence of the presence of vegetable growths in the false membrane. But in 1880, the eminent English fungologist, Rev. John E. Vize, M.A., published a paper, in which he strongly maintained the dependence of diphtheria on an oïdium.

More recent investigations tend to show that diphtheria is an infiltration of living tissue with micrococci, and that their development is intimately associated with the morbid process. From an address of Dr. Michael W. Taylor, of Penrith, published in the *British Medical Journal*, July 2d, 1881, it would seem that the pseudo-membrane consists of layers of stratified epithelium, more or less mingled with products of exudation from blood plasma and some micrococci, while in the submucous tissue the channels communicating with the lymphatics are filled with micrococci, or masses of vegetation. This would seem to encourage the belief that the disease is due to the development and active life of vegetable matter within the body. The most recent investigations on this subject have been made by Professor H. C. Wood and Dr. Henry F. Formad, of Philadelphia. They were conducted at the suggestion and under the auspices of the National Board of Health. After many experiments, they have reached the conclusion that *micrococci* are the *fons et origo mali* of diphtheria.

Thus much, therefore, we know, and no more. It is truly little enough, but it gives promise of more in the future. We know that diphtheria is caused by a parasitic vegetable growth in the body. The most valuable research now in order will be to endeavor to discover some agent capable of destroying the vitality of this growth, from which we may be able to devise some means of preventing the disease. Medical journalism contains many discussions as to the origin of the micrococci of diphtheria. Some maintaining the doctrine that they are produced as a direct result of vegetable decomposition, while others stoutly deny this proposition. Whether they are or not is of but little real practical value as long as they exist. When a man breaks his leg a sensible surgeon will set it first and inquire how it happened afterwards. So it will be better for ex-

perimenters and investigators to devise first some effectual means of destroying the vegetable parasite and subsequently determine its origin. In connection with the etiology, we may state that the weight of evidence is in favor of the doctrine that diphtheria is a blood, or systemic, or consti tutional disease, and is contagious. We may also allude to the fact that some observers have endeavored to establish an identity between croup and diphtheria. The weight of evidence is also against this affinity, and justly so, since croup is proven to be a sthenic, while diphtheria is undoubtedly an asthenic disease. It will be of interest to note some of the means by which the disease may be carried. It was stated at the recent International Medical Congress that seven epidemics of diphtheria were traced directly to infected milk. Five hundred cases were clearly shown to be due to drinking infected milk. If the disease is due to micrococci, then it is self evident that it can be communicated by any medium capable of carrying these micrococci, and we must say that the same channels of infection exist for diphtheria as for smallpox. But, in his recent work on this disease, Dr. JACOBI takes ground against the germ theory. So much for our minute researches into the realms of microscopy. One man or a set of men erect a structure of experiments upon the summit of which he places the resultant fact ; when along comes some iconoclastic investigator, whose name and fame are great, who, with one blow, topples the structure to the ground (just when the rank and file were about to accept it), denies the truth of the theory, and either advances a new one, to make confusion worse confounded, or leaves us without any explanation, thereby increasing the doubt in our minds and causing us to wonder whom to believe. To sum up, then: We have no accurate knowledge concerning the nature of the causative agent of diphtheria, but the weight of evidence is in favor of the theory that the disease is caused by the entrance into and the development and multiplication of micrococci or parasitic vegetable bodies in the system. There is more unanimity in the fact that the disease or these spores can be communicated from one person to another or can be carried by any vehicle or through any channel, just as the poison of smallpox can be.

Pathology.—Very little additional information has of late years been contributed to the pathology of this disease, the greatest efforts having been directed towards elucidating its etiology. The disease is admitted to be a constitutional affection, with the seat of its most important symptoms in the throat. It has been demonstrated by the experiments of Professor WOOD and Dr. FORMAD (already referred to), that a severe inflammation of the trachea would produce a false membrane identical with that produced in diphtheria, with the only difference that micrococci were not so abundant in it. Therefore, they argued that there was nothing specific in the simple production of false membrane. From which we are led to conclude, that while this disease exhibits its recognizable and distinctive phenomena in the throat, yet the morbid changes which render it so dangerous an affection are produced in the blood, and are not yet clearly understood. In support of this view, we might quote the result of some experiments made by Dr. FORMAD, at Ludington, Michigan, during the prevalence of an epidemic of diphtheria there. Some animals were inoculated with the exudation from human beings. They sickened and died in a few days. The blood, examined during life and after death, contained micrococci, similar to those found in the blood of the diphtheritic children of Ludington. It was shown, in the course of these experiments, that the micrococci first attack the white blood corpuscles, which alter their appearance and lose their granulations. They finally become full of micrococci, and ultimately the corpuscle bursts, when its contents escape as an irregular, transparent mass, full of micrococci, to form the so-called zoöglea masses. The bone marrow was found full of leucocytes and cells containing micrococci. This same condition, as well as similar symptoms, were observed in the cases of diphtheria in children, which determined the identity of the natural and artificially produced diseased conditions. These results tend to prove the fact that diphtheria is a constitutional disease, and the profound demoralization of the blood which exists will readily explain the serious nature of the disease.

This altered and degenerated condition of the vital fluid will likewise make clear the cause of the serious after-effects so often found in this disease. To epitomize: while the ordinary diagnostic pathological phenomena of diphtheria are seated in the throat, the significant and dangerous morbid changes take place in the blood, and consist of degeneration of the white corpuscles (and most likely other and more important elements), induced by the presence of parasitic vegetable growths.

Diagnosis.—As may be anticipated from what has been said of the pathology of this disease, the most certain diagnostic points are to be found in an examination of the blood. Dr. FORMAD'S

experiments at Ludington resulted in the finding of micrococci in the blood of *every* case of diphtheria. In some they were free; in others they were found in the white blood corpuscles; while in a third class they were found in zoöglea masses; but, in some form or other, they were found in *every* case, and he must have examined a large number, since he tells us that "almost all the children had it," and Ludington has a population of over two thousand. Therefore, in the light of our present knowledge, it would seem safe to say that the crucial diagnostic point of diphtheria is to be found in the presence of micrococci in the blood. Taken in connection with the ordinary signs of the disease, the microscopic revelation of these parasites would render the diagnosis as certain as our present knowledge seems capable of making it. The ordinary symptoms of diphtheria, with which all are familiar, viz., sore throat, fever, and exudation, might occur from a simple, non-specific pharyngitis; but if, in connection with these familiar symptoms, we have great prostration, and a microscopic examination of the blood reveals the presence of micrococci, then can a positive diagnosis of diphtheria be made, with as much certainty as our existing medical knowledge warrants. This point is an additional argument of the necessity for every physician to possess a microscope and learn how to use it. This microscopic element of diagnosis is a very important one, and bears directly on the treatment. Because, if we possess a *certain* means of recognizing this disease in its *early stages*, we are much assisted in our treatment. Therefore, it behooves every physician who may be called to treat a case of suspected diphtheria, to at once make a microscopic examination of the blood and to record his experience, since by it we may be able to recognize and combat in its incipiency this fatal disease. The detection of the presence of micrococci in the blood is the only recent contribution to the diagnosis of diphtheria, and if found, by more extended experience, to be universal, it constitutes all that we require, since it will, if always present, furnish us undisputed and undoubted evidence of the nature of the disease.

Treatment.—This is, indeed, a wide, and almost an illimitable field; as in the case of every other disease about which our knowledge is uncertain, nearly every remedy in the Dispensatory has been at times vaunted as useful in diphtheria. The time, no doubt, will come when we will possess a specific antidote capable of destroying the vitality of this diphtheritic parasite, and in this direction there is ample room for research and fame. But with our present knowledge, the treatment of this disease must be mainly the treatment of symptoms. Since it is essentially an asthenic disease, since it proves dangerous mainly by exhausting the strength, we must early resort to supportive treatment. No recent developments *of any note* have been made as to the treatment of this disease. Among those that have appeared we may mention mercurial fumigations as recommended and practiced by Dr. J. Corbin (*see Half-yearly Compendium Med. Science, January*, 1882, *D. G. Brinton*, M.D.); pilocarpine muriate recommended by Dr. H. F. Williamson (*see the same*), and the use of electricity by Dr. G. K. Smith (*same*). While these various remedial agents may and probably do have *some influence* on this disease, yet our therapeutic beacon leads us to look for some agent possessing the power of destroying the vitality of the parasitic growth which causes the disease, and until such a discovery has been made, we can only *temporize* with the ravages of the poison, support the patient's strength and treat symptoms as we find them. The *Compendium* (already referred to) contains a quotation from the *Bull. de Therapeutique* on the *local* use of *papaine*, the extract of the *carica papaya*, in diphtheria. It is deserving of notice and commands further investigation. In relation to it, Dr. Bouchut stated to the French Academy of Medicine "that a piece of diphtheritic membrane, thick, elastic and resistant, if placed in a 33 per cent. solution of papaine, will be dissolved in a few hours in the cold; heat effects solution in a few minutes. If a piece of moist fibrin be touched for an instant with the solution, it retains the power of dissolving and forming peptone, even though afterwards washed in a stream of water for several hours. These experiments suggested the topical use of papaine in diphtheria. It was found, however, that solution takes place much more slowly when the membranes are still attached to the living tissues, than when in a test tube; nevertheless, the treatment has been tolerably successful and is worthy of a further trial. Dr. Bouchut applied it in thirty-two cases, in children and adults, with four deaths" (a very gratifying result). "The fluid must be applied every two hours." When successful "it gradually softens and disintegrates the exudation and causes it to disappear in from three to five days." This experience of *papaine*, with the proportion of cases apparently in its favor, from a reliable authority, would entitle it to consideration, and further research into its curative or diphtheritic preventive power should be encouraged. *To*

summarize: We possess no specific for diphtheria. Our treatment must be that of symptoms as they arise, combined with a general tonic plan. We can only hope to successfully combat this fatal disease when we have discovered a remedy capable of neutralizing or destroying the vitality and activity of the poison producing it.

Abortive Treatment.—In conclusion, an interesting point has been raised by an English physician, as to whether a threatened attack of diphtheria can be aborted. He had experience with two cases who, after exposure to diphtheritic contagion by nursing fatal cases of the disease, were taken sick, with symptoms resembling those of diphtheria. The patients were seen very early in the attack and were put to bed, under an anti-febrile course of treatment, with tonics and local applications, or astringent gargles to the throat. No *special* line of treatment was observed, quinine, iron, chlorate of potash, and alcohol, being the chief means employed, and in each case what threatened to be an attack of diphtheria resulted in complete recovery in a few days. Of course, these two cases are insignificant in establishing a law that this disease can be aborted, but straws tell which way the wind blows, and if further observation proves that we can, by appropriate measures, prevent an attack of diphtheria, this observation of our British brother will assume due significance. He is careful to note the fact that if this disease can be aborted, it can only be accomplished by seeing the patient very early in the disease, before it has become developed to any extent.

In continuation of this report on Infectious Diseases, we will next week discuss the most recent developments concerning *Scarlet Fever.*

(To be Continued.)

Correspondence.

Reducing Fractures without Pain and without Anæsthetics.

Ed. Med. and Surg. Reporter:—

Many years ago, R. W., a boy of fourteen years of age, fell and experienced a fractured arm. It proved a Colles fracture. Splints were applied and held in place by ties of strong tape. In four weeks, to all appearance, the limb was restored to symmetry and health. The dressings were removed and the arm and hand were slowly brought into every day use.

A week later my attention was called to it. To my mortification, there stared at me all the original deformity seen at the moment of the accident. What had happened? Nothing! The lad used it as he found occasion, and with no particular occupation. Gradually, the bony displacement had returned, in mockery of chirurgical therapeutics. The injury was now five weeks old. What was to be done?

We have all heard of broken limbs in malposition being purposely broken over again. Such a course seemed irrational, indefensible, and therefore, unsurgical.

The splints were re-applied. This time, to the outside board from a cigar box was nailed an infra piece at right angles with the side piece; this basic splint was as wide as the thickness of the arm, to sustain the weight of the forearm and hand, and afford barely sufficient border to support the lower edge of the inside splint. The whole was tied firmly with two tapes, and supported in a sling. It was dressed and tightened up every one or two days.

The weight of the hand and the gradual painless pressure of the splints slowly corrected the ugly abnormal features, and in two weeks it was a satisfaction to witness all deformity had gone, and the member restored to natural shape. The mistake was in removing the splints prematurely.

Aside from recovering lost ground without harm, this case furnished important instruction, and outlined a new and better rule of practice. It taught how to dress fractures without inflicting pain, and without the use of anæsthetics. It taught how to dispense with what the writer now regards as the absurd proceeding of *pulling the injured part, to "set the bones."* That old first step is agonizing and needless. If splint pressure and position of limb will painlessly reduce fracture and deformity after five weeks' existence, why not employ them for that object in the outset, and avoid the flourish of setting garnished with screams? The simplest and easiest is the best. Therefore, for more than a decade, every case of fractured arm in my hands has been dressed in the manner above described, without pulling, without pain, without chloroform or ether, and without resulting deformity. With daily dressing, in a few days or a week apposition of the fragments is gradually and insensibly effected. As the swelling subsides the natural contour of the member is brought about, all in ample time. As a general rule, bandages to fractured limbs should be condemned and avoided. But the subject of absurd bandaging is sufficient for another article.

Stockton, Cal. A. S. Hudson, M.D.

Malformation of the Urethra.

Ed. Med. and Surg. Reporter:—

Authors on surgery state that malformations of the urethra in male children are exceedingly rare. I, therefore, take the present opportunity of reporting a case in which there was occlusion of the external meatus urinarius, absence of the frænum, and paraphimosis, in a male child, when it was born.

Mrs. Edward O., aged thirty eight, gave birth to her eighth child, a male, in which the above named malformation existed, at eight o'clock, A.M., of January 16th, 1882. Dr. J. P. Treacy, was her accoucheur. I saw the child, with Dr.

Treacy on January 17th. The child had not passed any urine since its birth, about thirty hours intervening. The child was fat, healthy, and otherwise well developed. All of Mrs. O's, other children are healthy and well developed. In order to remedy the occlusion of the meatus, I made a vertical incision with a bistoury, about one-eighth of an inch deep, and along the depression which was present over the meatus, and directed the nurse to use a small napkin separately over the penis, so as to be certain the child urinated *per via naturalis*. The next day, when I saw the child, with Dr. Treacy, we found it had urinated twice *per via naturalis*. The child has had no further difficulty in urinating. The swelling of the prepuce, which was present at birth, has now subsided, but paraphimosis still exists, and I think will continue to exist, as the prepuce is very short and covers the upper two-thirds of the base of the glans penis, like a hood. To-day, in my presence, while the napkin was off, urinated naturally.

John M. Batten, M.D.
73 *Sixth Avenue, Pittsburgh, Pa.*

A Case of Congenital Gastro-Diaphragmatic Hernia.

Ed. Med. and Surg. Reporter:—

This somewhat remarkable case occurred twenty-two years ago. It has been withheld, on account of the very imperfect observations which I was enabled to obtain.

I was called at 4 o'clock in the afternoon of the 15th of the third month, 1860, to see Elizabeth, a four year old daughter of Andrew Graham, living at New Garden. She had been, up to this date, a sprightly and healthy child; never having been seriously sick, or suspected of anything wrong in her organism.

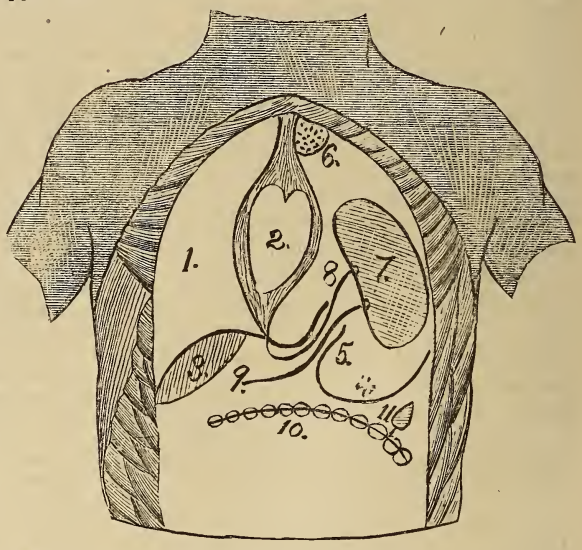
She ate her dinner as usual, but soon began to complain of pain in the stomach, and retching to vomit. I found her suffering severely from the pain, which she referred to the epigastrium, and the retchings were incessant. There was nothing raised from the stomach, and whatever she made an attempt to swallow was instantly rejected; and this continued to be the case until her death. She inclined to the position on her knees and elbows. Owing to a timid and fretful disposition, increased by an aged and indulgent grandmother, she would not allow me to approach her.

My early diagnosis was, stray worms in the stomach, which the result will probably justify. A few hasty and imperfect observations only could be made during life. Pulse very frequent and feeble; respiration hurried and laborious, with a marked elevation of the right shoulder; thorax was resonant on both sides; no tendency to cough.

As it was found impossible to give medicine by the mouth, recourse was had to enemata and external appliances for relief. The pain was, in a measure, amenable to the use of anodynes, but the retching never, till death relieved her, on the third day.

An imperfect and hurried post-mortem was obtained, under strict surveillance, just before burial. My notes are, consequently, as imperfect as my observations during life.

Nothing remarkable was observed in the cadaver, except a fullness in the left pleural and hypochondriac regions. When the abdominal viscera were brought into view it was apparent that there was a displacement or a negation of some of the organs. The liver was in situ; the stomach was nowhere to be seen; the left diaphragm was pressed down, presenting a strong convexity below, and depressing the transverse colon, to which the spleen was attached by loose tissue. On a closer inspection, there was found a circular perforation of the distended diaphragm, of an inch and a half diameter, with its edge rolled up into the thorax. Both the œsophagus and the duodenum were traced into or through this aperture into the pleural cavity.



1. Right lung. 2. Heart, pushed to the right. 3. Liver. 4. Left diaphragm distended. 5. Inflected tube, laid open. 6. Root of left lung. 7. Stomach (reduced to show the tube of the diaphragm). 8. Œsophagus. 9. Duodenum. 10. Transverse colon. 11. Spleen.

The thorax was then opened, when the character of the case became more apparent. The left lung was entirely wanting or only represented by a dark-colored button the size of half a walnut, at its root, in the apex of the cavity. The pleural cavity was wholly occupied by the distended stomach, with its cardiac extremity upward, and the large curvature resting against the costal pleura. It was now seen that the involuted margin of the aperture in the diaphragm was carried up in the form of a delicate tube, inclosing the œsophagus and duodenum, for more than two inches. The stomach was greatly distended with gas, pressing the diaphragm downward, and pushing the heart over toward the

right side. In addition to the gas, the stomach contained a few ounces of mucus, and broken down food, and eight large, living, lumbricoid worms, thus verifying the diagnosis. There was no effusion of serum, or of coagulable lymph, or morbid adhesions to be found in any part of the body, to indicate inflammation, either past or present.

It is difficult to draw satisfactory conclusions from this very imperfect, though faithful narrative. Certainly nothing in the previous history of the child, or in the pathological phenomena observed during her illness, would have led any one to anticipate the existing state of things, as revealed by the autopsy, nor would it have availed anything to have known it. It must, I think, be obvious that this displacement was congenital The abnormal condition could not, by any possibility, have occurred within the last three days; and there was no post-natal record to which it could be referred. Whether should we refer it to an original defect in the primordial germ? or may it have been caused by some severe prenatal concussion, or compression, of the early and nascent embryo?

Every physician is aware of the extreme irritation which is produced in the stomach by the sudden irruption of a few worms into it. It is not so easy to comprehend how so many large worms should have thus suddenly found a passage through the deflected duodenum. Yet, while in health, the passage must have been quite pervious. They may have become entangled in a ball, or knot, as they sometimes do, and in that condition entered the stomach. We only have the fact of their presence. The gas in the stomach may have originated, more or less, from post-mortem changes.

E. Michener, M.D.

Sylvania, Chester Co., Pa.

News and Miscellany.

The Horrors of Smallpox.

A secular paper gives a graphic description of the horrors of this terrible disease. Recently, in Jersey city, a shoemaker died of the disease, and when the health inspector visited the house, he found the following horrible sight. The wife was lying on the floor on a bundle of rags, suffering with the disease, while on either side of her lay a child, dead from smallpox. In the corner of the room a third child was ill with it, while the remaining two were cuddled up to a small stove, but had not yet been attacked.

Medical Ethics in France.

The Société Médicale de Nievre have recently drawn up a little code, which our American brethren would do well to imitate. It runs as follows: 1st. Medical men honor their profession by honoring themselves in their confraternal relations, and, consequently, by observing, in their mutual intercourse, the greatest courtesy in actions and in words. 2d. Every medical man called in accidentally to a patient who is under treatment, in the absence of the usual medical man, should restrict himself to prescribing the medicines necessary for the moment, and not make any remarks upon the treatment which has been followed. 3d. He should not call again upon the patient, unless he be called in consultation by the medical man in attendance. 4th. Medical men called in consultation should abstain, while in the presence of the patient and of his friends, from any expressions that may prejudice the usual medical attendant. In private consultations, that is to say, between the medical men only, any expressions which may throw discredit on either of the consultants is reprehensible. The treatment agreed upon by the consultants should be carried out by the usual medical man. 5th. The consulting medical man should not go to see the patient, unless he be again called in, or authorized to do so by the medical man in charge.

Smallpox in Philadelphia.

According to the Health officer's statement, smallpox is rapidly getting under control in this city. Strange to say, and contrary to precedent, the disease has diminished since the advent of the cold spell. As high as twenty new cases have been reported in one day, and from seventeen to nineteen have been the rule for some time past. But on the twenty-third instant, only thirteen were reported, and there has been a rapid decline, so marked that on the twenty-fifth not a single new case was reported.

A Good Way to Increase Smallpox.

One day, recently, seven tramps, broken out and covered with smallpox, who had come from other cities, boldly walked into the Health Office in Chicago. On the same day, a man who had just arrived from New York, whither he had come from Germany, walked into the same office, with a very bad attack of the disease. Such carelessness seems like tempting nature, and must ever be rewarded by a plentiful crop of disease. There is only one way of preventing such criminal negligence, namely, by strict legislation, rigidly enforced.

Insanity a Cause for Divorce.

A recent decision in an English divorce court is of interest in this connection. The first cause for the husband to suspect his wife's sanity occurred on the nuptial night, when she refused to allow the marriage to be consummated. He sent her home. Subsequently she was examined by several physicians, who agreed that she was afflicted with melancholia, and was not in fit condition, mentally, to enter into a marriage contract. The court held the same view, and declared the marriage null.

Anti-Vaccinationists.

The London *Lancet* says, "The Anti-Vaccinationists at Dewsbury, recently organized a demonstration against the vaccination officer. Two brass bands, torch bearers, sensational pictures, and an effigy of the obnoxious official, had part in the demonstration. He was one of the most amused of the spectators."

Personal.

—M. Charles Richet has lately made a communication to the Paris Société de Biologie, in which he seeks to show that after the death of an animal the nerves of sensation retain their functions longer than the nerves of motion.

—The Wyatt-Edgell prize, offered in England, of £200, for the best essay on the "Range of Heredity in Health and Disease," has been awarded to Mr. George Gaskoin.

—Dr. John H. Ross, a leading physician of Kokomo, Ind., recently caned the editor of a secular paper, on account of an article published by him.

—Dr. J. S. Billings and Dr. H. J. Bigelow have been elected honorary members of the London Clinical Society.

Items.

—Messrs. Dickinson, of Broad street, London, are painting a large group picture of the garden party given by Baroness Burdett Coutts to the International Medical Congress, in August last. The picture will contain about one hundred of the leading visitors and presidents of sections. When completed, no doubt it will be engraved. Such an engraving would make a handsome ornament for the wall of a doctor's office.

—A young woman, who had a peculiar affection of the face, for which she persistenly refused to allow surgical interference, died recently, in Virginia. Her grave was robbed, but for what purpose is not stated, although the circumstances of the case would seem to implicate the physicians of the neighborhood.

—A midwife in England was committed recently for trial for manslaughter. She had, it was alleged, conveyed puerperal fever from one patient to another, and death resulted in the second case.

—The Rochester *Express* tells about a very deaf man, who, being admonished on a very cold day, that if he did not protect his ears they would freeze, replied, "Suppose they do, they're no good."

OBITUARY NOTICES.

DR. BRIERRE DE BOISMONT.

We have just heard of the death of this eminent alienist, in his eighty-fifth year, at St. Mandé, where he had for some years lived in retirement. He was one of the founders of the Medico-Psychological Society of Paris, of which he was also one of the most zealous and eminent members. His contributions to the literature of insanity were very numerous and authoritative.

DR. F. MEYER.

Dr. F. Meyer, a leading physician of Bucyrus, Ohio, died recently, having suffered from nervous disorders for six years. He was a native of Germany, occupying the rank of a Count during the revolution of 1849. He espoused the Liberal cause, and with many others was forced to leave the country. He came to America and settled in Bucyrus, and for many years had an extensive practice as a physician.

DR. MAURICE BEESLEY.

Dr. Maurice Beesley died at his residence in Dennisville, N. J., recently, in the seventy-seventh year of his age. His death was caused by general debility. He was born at Beesley's Point. He was the representative of Cape May County in the New Jersey Legislature for four years, and was, until last summer, when he resigned on account of failing health, Superintendent of Schools for Cape May County, which office he held from its creation. He was one of the oldest graduates of the University of Pennsylvania, and has been practicing medicine in Cape May county for the past fifty-five years. He was the author of several works on geological surveys, and was considered an authority on the boundary lines of the sunken forests and cedar swamps in that county.

QUERIES AND REPLIES.

Dr. M. H. S., of Pa., asks us whether the Philadelphia County Medical Society will admit female physicians. Also, whether they have removed the restriction from allowing their members to consult with professors in the Woman's Medical College.

Answer.—1st. The Society have decided to admit to membership all qualified female practitioners that may apply. 2d. Such a restriction never existed. The President of the Society is a Professor in the Woman's College.

A subscriber asks for a working formula for using gelatine as a suppository.

Answer.— ℞. Gelatin, 1 part
Glycerine,
Water, āā 2 parts. M.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

EXTRAVASATION OF URINE.

BY FESSENDEN NOTT OTIS, M.D.,

Clinical Professor of Diseases of the Genito-urinary System, in the College of Physicians and Surgeons, New York.

(*Concluded from page* 114.)

Gentlemen:—It has now been five weeks since we operated upon a case, on Blackwell's Island, for extravasation and infiltration of urine. Some new features of interest have developed since I last spoke to you about the case, and I will again call your attention to it to-day. The patient was doing very well for a while after the operation, when, on the eighth day, a profuse hemorrhage occurred, and by the time I reached the patient he was pale, the pulse was rapid, and his condition was such as to require free stimulation. Blood was still flowing from the bladder and penis, although a superficial plug had been introduced and ice applied. The patient was straining to evacuate the bladder, which was filled with blood clots. I passed a large-sized catheter into the bladder, attached to it a syringe, washed out the bladder, then introduced a canula-chemise through the wound into the viscus, to stop hemorrhage. The canula-chemise was made by passing a catheter through a snugly-fitting hole in a piece of linen about ten inches square, then tying the cloth about one inch from the eye of the catheter and turning it forward, making a sort of umbrella. This is rough and lies in folds, so that it causes the patient a good deal of pain in introducing it through the sensitive wound; and on this occasion it occurred to me to smear the cloth well with hard soap, and with soap also to fill up the shoulder at the junction of the cloth with the catheter, after which it slipped into the bladder readily. If this does not check hemorrhage, the folds of the umbrella may be opened and lint or cotton packed around the catheter, and a sufficient amount of pressure be thus exerted to accomplish the object desired. Then fever set in, which was accompanied by profuse sweating. It was then found that a pus cavity had formed in the tissues of the abdomen, and some infiltration of urine could be recognized by the crepitus resulting from its decomposition. The manner in which infiltration of urine may take place in one part and not involve another is illustrated in this simple but ingenious manikin, which shows the division between the superior and inferior, the anterior and posterior penile portions, the relations of the deep and superficial perineal fascia, the triangular ligament, the scrotum, vas deferens, etc. An incision was made, about two inches in length, in the line of the groin, laying open a cavity filled with very fetid pus. A drainage tube was then introduced and the pus cavity washed out with a solution of carbolic acid, about 1 to 100. The patient did very well for some days, but fever again was set up, there was more or less profuse diaphoresis, and on examination another pus cavity was found in the tissues of the scrotum. An incision was made into this, after which the case went rapidly on toward recovery. When I saw the patient a week ago he was passing most of his urine through the natural channel, only a little dribbling through the opening in the perineum. This was very satisfactory, but a few days later the urine came less from the

urethra and more through the perineal opening, the cause of which was found to exist in an obstruction to the flow of urine through the natural channel. Now, this is an accident which often occurs when an opening is made through the perineum into the bladder for any cause, as, for instance, for the removal of stone, and the perineal opening is then slow in healing, sometimes constituting a permanent fistula. When this occurs, I think it will be found that, in ninety-nine cases out of a hundred an obstruction to the flow of the urine exists in the anterior portion of the urethra. This is true, too, in cases in which there has been no antecedent disease. In cases where there has been perineal section for stone, for instance, and in which there has been no antecedent gonorrhœal disease, we may yet have obstructions, strictures, resulting from the same causes which have produced the stone, namely, lithiasis. The presence of calculous material passing through the urethra irritates it at certain points, which, when continued, produces such an inflammatory condition as results in the accretion of plastic material at this point, constituting stricture. Whatever different theories may be entertained with regard to the cause of stricture, I think we must necessarily, in taking a common sense view of it, come to accept the simple explanation of plastic material being drawn to the point at which irritation exists, from whatever cause; not necessarily irritation the result of specific disease, but irritation from any cause whatever, will produce stricture, provided it exist in sufficient intensity and long enough to cause the deposit of plastic material at this point.

You will remember that I attributed the cause of this patient's difficulty to a folliculitis supposed to exist behind a stricture, for there was no other way to account for it. The patient, however, had had for a number of years a certain amount of urethral discharge, but to which he paid no attention. He had no difficulty in passing his urine until this swelling occurred in the perineum, therefore we could only attribute his difficulty to the cause which I have already named, that is, follicular perforation of the urethra, the result of a folliculitis existing behind a stricture. You will bear in mind the fact that a stricture even of large calibre is capable of holding behind it the solid material of the urine, which may give rise to irritation, and this again to inflammation in a follicle in which suppuration takes place and penetrates the urethral wall, and allows, in many instances, urine to pass through into the tissues. Now as soon as this takes place, of course, inflammation is set up by the presence of urine, and an abscess of greater or less size is formed. The follicular penetration may be so small that the urine can extravasate only in very small quantity, in which case only a very slight and localized inflammation will result, and about this a sufficient amount of plastic material may be thrown out to consolidate the parts and leave a little, hard bunch. But where the opening is larger, urinary infiltration of the tissues takes place more abundantly in proportion to the size of the opening, and then the progress toward extensive destruction of tissue goes on rapidly.

The examination of the patient in the present case sustained the above views. In the first place, the urethral orifice was of small size, and we consider this contraction of the orifice a stricture. Anything which contracts the normal calibre of the canal permanently may be considered a stricture, as far as its effect upon the passage of the urine is concerned. Then, behind the contracted orifice this patient had three points of stricture within a distance of two and a half and three and a half inches, which, being measured, were found equal to ten millimeters. This degree of contraction was determined by the proportionate measurement, which always holds true, between the circumference of the penis and the size of the urethral canal. In this case the circumference of the penis was three and a half inches, which called for a urethra which would admit an instrument No. 35 French.

The measurement of the canal was made with the urethrometer, an instrument which I will briefly describe for the benefit of those students who may not be familiar with its working. The urethrometer has at one end a bulb, which expands or contracts synchronously with the movement of a screw at the other end. When closed it usually represents 15 French, and when the bulb is completely expanded by turning the screw at the other extremity it represents 45 French, or by turning the screw less, it may be made to represent any number between these two extremes. The end of the instrument is covered by a small rubber stall, which protects it and prevents folds of mucous membrane getting between the arms of the instrument and becoming pinched. The instrument is usually composed of springs, but the one which I show, being of older date, is composed of hinged arms; but the two kinds work on the same general principle. The degree of expansion or contraction of the bulb is indicated by a dial at the screw extremity.

This instrument was passed down to the bulbo-

membranous portion of the urethra and turned up to 34 French, which was about the proportionate relation between the size of the penis and of the urethra in this case. The bulb was then gently drawn forward until arrested, when it was lessened by turning the screw until it passed through the contraction or stricture, then again turned up to the normal size, but again twice turned down to pass through two more strictures which existed within an inch and a half or two inches and a half of the former one. Let me remark here, that there exists a normal difference of two millimeters between the size of the bulbo-membranous and the middle portions of the urethra.

The first stricture in this case was found just over the scrotum, which fact would suggest that perforation had taken place here, and would account for infiltration first occurring in the scrotum. If you will recall the arrangement of the fascia, as illustrated in a manikin shown at a former clinic, which made a division into anterior and posterior penile chambers, you will understand how infiltration of urine in the posterior part may be entirely separate from infiltration into the anterior part, and hence, involvement of the scrotum, without that of the body of the penis, as occurred in this case. From the scrotum the urine found its way through the cribriform fascia up into the groin and integument of the abdomen.

While, therefore, we cannot ascertain positively that there was a follicular opening which led to the trouble in this case, I think we may, by exclusion, conclude with reasonable certainty that such was the case, and while before extensive infiltration of the tissues occurred through this abnormal departure in the urethra, which was relieved by operation, the same pathological state now prevents closure of the perineal opening.

Yesterday I passed a dilating urethrometer down the urethra and divided these strictures. This instrument consists of a pair of very small bars, connected by short arms, very much after the plan of a parallel ruler. In the principal bar a knife is made to run in a groove, which extends from one end to the other, and at the extremity is a slot, which conceals the knife when the blade is passed into the end of the instrument. These bars are capable of being separated to a point representing forty-five millimeters French, corresponding to the scale of the urethrometer.

Now, when you come to understand the nature of every stricture, as I have previously described it to you, that is, that it is made up of plastic material which goes on to be fibrous, possessing all the qualities which we recognize in cicatricial tissue, that is to say, density, firmness, and a certain amount of resiliency, you can then understand that unless this is fixed in some way, the knife, in passing across the stricture, will not be likely to sever it, any more than if it were drawn across a loose rubber band. Consequently, in order to divide a stricture, we must fix it, make it tense, and as thin as possible, so that it can be divided with a narrow blade. This principle may be illustrated by putting a rubber band rather loosely on the dividing instrument. When we find that, instead of being divided, the band stretches and allows the blade to pass through without severing it. If, in drawing the blade through a stricture, you meet with considerable resistance, remember that this instrument is not a divulsor; you should not use too great force, lest the instrument break, but push it back and release it, and try again, and if necessary draw the blade through two or more times, only at the last time turning the dial up to the full size of the urethra. When the stricture is completely divided, as is illustrated by the division of this rubber band; there remains no obstruction at that part of the canal whatever, and a sound, either bulbous or other kind, can then be passed down without the least difficulty. Then, if the stricture has been completely divided and the lips of the wound are kept entirely separate until healing has taken place, we find no tendency at all to a recurrence of the stricture. Therefore, as a rule, to which there are not many exceptions, this operation has the advantage of resulting in a complete and thorough cure of the stricture.

This plan of treatment of such perineal openings as do not readily heal is not novel. I have many times had occasion to demonstrate the fact that perineal openings, however made, are, in cases in which they do not readily heal, kept open by an obstruction in the urethra, anterior to the perineal wound. While passing through the Lock Hospital, in London, several years ago, in company with Mr. Coulson and Mr. Teevan, two of the surgeons of the hospital, we were discussing the subject of stricture, particularly with reference to strictures of large calibre, and Mr. Coulson called my attention to a certain patient, saying that he had been in the hospital for a long time; he was suffering from a perineal fistula, which they were unable to heal. Previous to his entrance into the Lock Hospital he had been at Guy's, St. Thomas', and other hospitals in London, where he had undergone almost all the known procedures for the closure of his peri-

neal fistula, but without success. Three months later an account of this case was published in the London *Lancet*, August 20th, 1875, under the title of "Perineal Section, followed by the operation of Dr. Otis, for the Cure of Fistula in the Perineum," by Walter Coulson, F.R.C.S., surgeon to the Lock and St. Peter's Hospitals.

After giving the previous history of the case, he says: "The perineal wound became merely a fissured opening, but still it would not quite heal, and on every occasion that the patient passed water some portion of the urine escaped through the fistula. *The question then presented itself, whether the fistula might not possibly be kept patent by some constriction in the penile portion of the urethra?* With the assistance of Dr. Otis, an examination was made with the urethrometer, *and the existence of three distinct points of stricture was demonstrated.* It was, therefore, resolved that resort should be had to his operation. The patient was placed under the influence of ether, administered by Dr. Knott, and the urethrotome of Dr. Otis was passed down as far as the fistula. The instrument was then made to indicate a dilatation corresponding to 32 of the French scale, and the three points of contraction were freely divided. The last mentioned result was verified by the introduction of the bulbous sound (32), which was passed down as far as the fistulous opening, and withdrawn without a catch. A tube, open at both ends and about five inches long, was tied into the urethra after the operation, and was allowed to remain for six hours. This was at the suggestion of Dr. Otis; but the tube was removed at the patient's request, as there was no sign of bleeding: the loss of blood after the operation was also slight. From the date of the operation, July 19th, to the 24th, no unfavorable symptom manifested itself. A 32 bougie was daily passed along the urethra, to prevent adhesion of the cut surfaces, *and the patient left the hospital cured.* When he reported himself to me, August 16th, *the fistula was completely healed.* Among the complications arising from stricture, extravasation of urine, and injury to the urethra, there are few which occasion more inconvenience to the patient, and trouble to the surgeon, than perineal fistula. In D.'s case the complication resulted from an operation performed for the relief of extravasation, and dilatation having been tried and failing to close the fistula, perineal section was, for a second time, resorted to; but in spite of this operation, and subsequent dilatation, the fistula remained open."

"The result of Dr. Otis' operation certainly proved that slight contractions, which are not usually recognized as strictures, may offer obstruction to the passage of the urine sufficient to prevent a urinary fistula from healing. The result of the internal division of the strictures and the daily introduction of full-sized instruments left the mucous wall of the canal, after complete cicatrization had taken place, as supple and non-resisting to the passage of the full-sized sound as a perfectly healthy urethra."

Such is the testimony of so eminent an authority as Mr. Coulson, with regard to the complete absorption of stricture material after division by this method.

The subject is one of such great importance that I deem it proper to quote another case which was reported by Mr. Teevan, Surgeon to the Lock and St. Peter's Hospitals, and published in the *British Medical Journal* of October 21st, 1876: "*Traumatic Stricture and numerous Penile Fistulæ Cured by Internal Urethrotomy.*" Mr. Teevan related particulars of the case. The patient was a sailor, who had injured his scrotum and penis by a fall twenty one years previously. Numerous abscesses formed and sixteen fistulæ resulted, through which all the urine was passed. In the course of a few years the fistulæ in the scrotum (eleven in number) closed, but those in the penile urethra remained open. For a period of more than three months Mr. Teevan tried three separate plans of treatment, with but partial success. First, retaining a catheter in the bladder. Second, the patient drawing off all his own urine with a catheter for two months. Third, the application of heated wires and probes tipped with nitrate of silver. On January 6th Mr. Teevan performed Dr. Otis' operation, and *nine days afterward all the fistulæ were closed*, and remained so permanently. The points of interest in the case were:—

1st. The stricture being a traumatic one of the worst description.

2d. The fistulæ being in the penile urethra, always most difficult to cure.

3d. The fistulæ having been open for the long period of twenty-one years.

4th. The failure of three different methods of treatment.

5th. The permanent closure of the fistulæ after the strictured portion of the canal had been enlarged by Dr. Otis' urethrotome *to its natural calibre*, which was 31 millimeters in circumference.

6th. Subsequent to the operation no catheter was left in the bladder, nor was the urine drawn off.

[At a subsequent clinic, Professor Otis stated that the patient had entirely recovered, and although he had not yet left the hospital, he was walking about the wards.]

Communications.

THE THERMOMETER AND ITS USE IN MEDICINE.

BY HUGO ENGEL, A.M., M.D.,

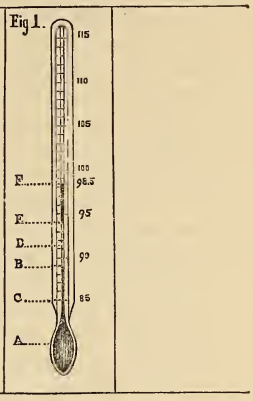
Professor of the Principles and Practice of Medicine and of Clinical Medicine, at the Medico-Chirurgical College, etc., etc.

It must be admitted that there are still many, and especially older physicians, who in their daily routine practice do not make use of the clinical thermometer. Though often, perhaps, excusable, they are wrong in not doing so, and without knowing it, they harm their reputation by such neglect. First, the physician who employs all modern modes of investigation in the examination and treatment of his cases, will always make a better impression upon the public than the one who, with an earnest face, simply looks at the patient and the tongue, feels the pulse, and asks a few questions. But there is another point which should induce every practitioner to use all modern appliances in the performance of his professional duties, and especially the thermometer, and that is the rapidity and certainty with which the latter frequently enables the physician to recognize a disease, or to give a sure prognosis, while without the use of this instrument he may have to wait days for the development of other symptoms, ere he can arrive at a definite conclusion. I said above, that many physicians are excusable if they do not use the thermometer, and so they are. When they studied medicine, the application of this instrument in disease was not known as yet, and therefore, not taught. Later, especially if practicing in the country, they had no opportunity of becoming acquainted with its use. To remedy this, I shall endeavor in the following to describe the best clinical thermometer, which every physician should possess, then show how it is best employed, and lastly, try to prove its great value in the diagnosis and prognosis of certain diseases which may any day come under the care of the practicing physician.

The physician should buy only a *self registering* thermometer. The following cut (Fig. 1) gives a good illustration of it.

A is the bulb of mercury, which ascends here as a fine column, C, up to B. From B to E is a hollow space D, filled with air, and this column of air, D, divides the upper column of mercury E.....F from the lower one, ending at B. The physician has only to do with this upper column of mercury E.....F. A scale is cut into the glass and the thermometer should indicate at least the degrees of temperature from 85° to 115° Fahr. Each degree is generally subdivided into four or five parts. The way the instrument works,

Fig 1.



is the following: A self-registering thermometer is made by using an ordinary thermometer tube, with a very fine bore, and then breaking the mercurial column at one point by the insertion of a small portion of air. When the temperature causes the mercury to expand, the air is carried forward, and, of course, pushes the mercury above it forward also. When, however, the temperature falls, the lower column of mercury contracts, the air between the two parts expands, being relieved from pressure, and thus keeps the index (the upper mercurial column) in its original position, being also assisted by the capillary attraction of the small tube on the index column. The lower column can ascend to the same point as the upper did, provided the temperature is proportionately increased, but the register being arranged for the length of the entire column, any shortening of it by the separation of a portion for the index will necessarily require a much greater expansion of the remaining portion in order to occupy the same space.

The reader will easily see, therefore, the reason why the upper or index column of mercury indicates the degree of temperature to which the instrument has been exposed, and why it will continue to register the height once reached, unless it is brought in contact with a still higher temperature than the one it records, or is forced down by the physician, as will soon be mentioned.

A physician should buy a clinical thermo-

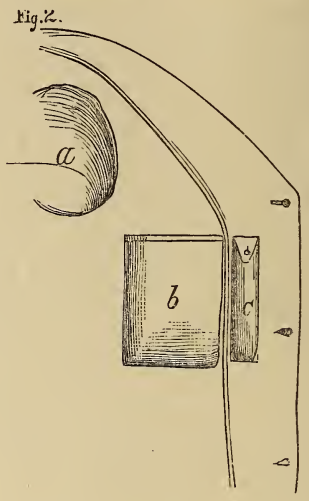
meter—as the one just described—from a first-class firm only, and secure an English imported one, which is accompanied by a statement of the Observatory at Greenwich, certifying, usually, that the instrument varies only $\frac{1}{100}°$ or so, therefore, so little, that its reliability for medical purposes is not influenced thereby. The price for such instruments varies from $4.50 to $5.50; if higher, the case is of silver, or otherwise specially valuable. But there are very good thermometers made in our country also, and they can be had for from $1.75 to $3.50. If the physician, however, buys an American thermometer, he should send the same, by mail, to the Observatory of Harvard University, to have it tested. They charge only twenty-five cents for the testing, and the great necessity of having this done is proven by the fact that the Harvard Observatory has tested already hundreds of American thermometers, which varied from $\frac{1}{2}°$ to over 2°, and the authorities there have publicly stated that the majority of American thermometers vary over $1\frac{1}{2}°$. Such an instrument most certainly is useless, nay, even dangerous. The fact of so many being incorrect proves the necessity of having every clinical thermometer tested by the Harvard Observatory, if it is not already accompanied by a certificate from a similar institution of equal reputation. If found to vary more than a small part of a degree, the instrument should be returned to the firm it was bought from, and an exchange, or return of the money insisted upon.

After the physician is in possession of a reliable, self-registering thermometer, which should be well protected by a metal or wooden case, lined with velvet, he must make arrangements for carrying it always safely with him. For this purpose I recommend, as the most useful, the following: The physician instructs his tailor to make him a small pocket, just large enough to hold the thermometer case, adjoining his inner coat pocket, and a lap with a button hole over the pocket, and sew on the latter a button, so that the pocket can be securely closed. The following cut (Fig. 2) will convey a better idea than any description can give.

Whoever does consider such an arrangement superfluous, has not been in the habit, as yet, of daily carrying with him a thermometer, because every one who has will have paid for at least half a dozen he broke, in a year. These thermometers seem to be endowed with a special tendency to fall out of any other pocket they are carried in, no matter how securely packed away, and I never have known any such thermometer *not* to break, when falling, *toute la même*, how small the distance; they seem bound to break. But the arrangement recommended cures them of their rather expensive habit.

Before using the thermometer, the physician should first convince himself that the upper column of mercury has not ascended above $98\frac{1}{2}°$. It should always be at least 2° below that, and whenever there is any suspicion of the patient's temperature being still lower, the upper column of mercury should not be higher than about 99°. If it registers a higher temperature than is desirable, before applying the thermometer to the patient, the physician should hold it by the

Fig. 2.



middle, tightly between his fingers, and knock with his hand several times on a hard substance (a table, for instance), or, taking the instrument securely with his fingers, by the top, make, several times in succession, a downward swinging motion with his arm, when the upper column of mercury (which, I mention once more, is the only one the physician has to look at) will sink down far below $98\frac{1}{2}°$. To inspect a self-registering thermometer and see that the upper column of mercury is not above $98\frac{1}{2}°$, is a point which never must be lost sight of before applying the instrument. Sometimes, when there is no doubt of the patient's temperature being increased, and when the upper index column is very low down, it may be well to dip the bulb into hot water, and bring the index up to $98\frac{1}{2}°$ before applying it. This is only a practical hint, a proceeding to save time.

The temperature of a patient should be taken twice daily, about 7 A. M. and 7 P. M., except in special cases, when it should be recorded at certain definite times of the day, as will be ex-

plained further below. The self-registering thermometer has in its favor, that if the temperature has to be taken twice daily, the physician need make his morning visit only, when he may himself take the temperature of his patient, and after bringing, by the above-mentioned procedure, the upper mercurial column down below 98½° again, leave the thermometer with the nurse, giving her directions how and when to apply it and to put it away for his inspection the following morning, when the self-recording instrument will inform him how high his patient's temperature was the night before. It is hardly necessary to mention here again that the instrument will only so long truly record the patient's temperature as it is not brought in contact with a still higher temperature than the one it is registering. If, for instance, the patient's temperature was 104°, and the nurse should lay the thermometer, even for a second only, on a hot stove, the physician must not be astonished to find it registering the temperature of the stove, or 115°, *i. e.*, as far as the column of mercury possibly could ascend.

No matter how the thermometer is applied, the application should last fully ten minutes. I specially caution physicians never to disregard this rule. Experience has often taught me that the index column in the last of the ten minutes would still ascend one degree or more, while after ten minutes I never have been able to observe an increase, except in cases like malaria, where the temperature often rapidly ascends in a very short time. But to determine the patient's actual temperature present, the application of the thermometer for ten minutes is sufficient, but necessary.

There are three ways in which, usually, the thermometer is applied: in the mouth, the rectum, or the axilla. Some prefer one way, some the other. But it is not always a matter of preference. For various reasons, as infection or danger of breaking (the patient's condition being such that he may bite the instrument with his teeth) the thermometer can frequently not be applied in the mouth, which is otherwise, if no special cause exists against it, a very good way of determining the actual temperature of the patient's body. The bulb must be put under the tongue and the lips closed over the thermometer, while the hand of the patient, physician or nurse holds the upper part of the instrument with the fingers. The patient is informed that he can swallow the saliva necessarily collecting during this procedure in his buccal cavity, but that he should do so without biting on the instrument, and without parting his lips. In most cases, however, where the patient is confined to his bed, the temperature is taken in the axilla. In such a case, the bulb and nearly the whole thermometer must be carefully laid deep in the armpit, and the arm pressed against the chest, so that the instrument is entirely surrounded by folds of the skin, and its upper part only to be seen. The patient should then be carefully covered by his under clothing and bed covering, while, for the purpose of greater security, the physician or nurse holds the point of the instrument between the fingers, as one can feel, this way, if the thermometer is well imbedded in the axilla and in intimate contact with the skin. But there are cases where the thermometer cannot be applied in the mouth, and where its application in the axilla would not give the correct temperature of the body. This happens in sunstroke, for instance. Here the patient is unconscious, and the application in the mouth would be attended with danger. But after the whole body has been rubbed with ice, or been lying in a bath of cold water for some time, it would necessitate a very long application of the thermometer in the axilla, ere it would indicate the actual temperature of the body. In such, and other instances, where, for some reason or other, the application can neither be well made in the mouth, nor in the axilla, the thermometer, after having been oiled sufficiently, is pushed into the rectum. It answers the purpose, if a little more of the instrument than the bulb is introduced. I remember especially, one grave case of sunstroke, where, notwithstanding rubbing the patient for about an hour, with ice, and throwing ice water over the chest (a bath could not be procured) unconsciousness still continued. The patient was rubbed thoroughly dry and a colleague present took the patient's temperature in the axilla. After having held it there securely for about ten minutes, the thermometer indicated 97°, and the physician who had not seen the case from the beginning expressed doubts as regards my diagnosis of sunstroke, and spoke of apoplexy. I quietly took the instrument, and after oiling it, pushed it up into the rectum. Within six minutes it recorded a temperature of 108°, and a somewhat sour smile crept over my colleague's face. Continuing, then, our process of cooling for about three-quarters of an hour longer, we had the pleasure of seeing the patient revive. While this case shows the necessity and importance of determining the actual temperature of the internal body, there are occasions when it is important to show the exact temperature of a certain limited part of the surface of the body.

For instance, to detect, in a case of hemiplegia, any difference between the temperature of the paralyzed and the non-paralyzed arm or leg, or to find out the temperature of a still more limited place, as in localized inflammations of the convolutions or other parts of the brain, there is a special *surface* thermometer made use of. The only difference between this and a common self-registering thermometer consists in the fact of the bulb containing the mercury being flat like a button in the surface thermometer, and being fastened, by a simple contrivance, into a leather strap, so that when the strap is tightened around the head, trunk, or a limb, the button-shaped bulb of the thermometer will be in intimate connection with and pressed on to that part of the skin where the local temperature shall be determined, while the upper part of the thermometer, with its scale, stands upright at right angles to the surface. These thermometers are also self-registering. They are very convenient for taking the surface temperature, or the temperature at any definite locality, as the physician needs not to hold the instrument between his fingers for ten minutes—the same length of time being, of course, here required, as in other cases; and as the button-shape of the bulb permits a better contact of the mercury with the skin, a more accurate measurement of the degree of heat is possible. The reader will see, from this, that a physician should be in possession of two self-registering thermometers; of the usual one, first described, and of the so-called surface thermometer. The latter, being rarely used, he need not carry it always about him, but may keep it in his office till occasion arises.

To recapitulate: A physician, when buying a self registering thermometer, should have it tested at the Harvard Observatory, if it is not accompanied already by a similar reliable certificate. If he does not wish to break the instrument frequently, he has a special pocket made for it, like the one described above. Before using the thermometer, or, if leaving it with an attendant to have the patient's temperature taken during his (the physician's) absence, he must always first convince himself that the upper (index) column of mercury registers less than $98\frac{1}{2}°$ (the normal temperature of the healthy human body), and should it not do so, bring the column down by the procedure mentioned. Usually, the thermometer may be applied in the mouth; if this cannot be done, in the axilla; and in certain cases, in the rectum. But no matter how the temperature is taken, the observation should be made at least twice daily, and for a period of not less than ten minutes each time. I may add, that the physician will do well to keep a record of all his cases, and that the number of respirations and pulse beats be noted each time the temperature is taken. For the small outlay of one dollar only, a record book can be bought, specially prepared for this purpose, and arranged for one hundred cases.*

We come now to an important question: Of what assistance is the clinical thermometer to the physician? And I answer, it is invaluable as regards diagnosis and prognosis. Certainly it will be impossible for me to mention the temperature record of every affection, but I will give in the following the most frequent diseases in which the use of the thermometer will prove of great value to the practicing physician.

A patient who has been losing flesh somewhat, of late, and been troubled with a short, dry cough, which no remedy seems to be able to remove totally, but in whom the physical diagnosis gives a negative result and indicates apparently a mild bronchitis only, which, however, cannot be cured; such a patient is in our charge. For a few evenings his temperature is taken in the mouth, or in the axilla, at about 6 P.M., and what do we find? The thermometer records regularly 99° to 100°. If no other cause exists for this regular nightly increase of temperature, the case can surely be put down as one of incipient tubercular phthisis, and if there should be a history of tuberculosis in the family, the diagnosis becomes a certainty.

The physician is called to a patient whose teeth chatter, who has had a chill. He may have been perfectly well before, or been so the day before, but had a similar attack one or two days previously, or there may be no history of any preceding illness whatever. The question arises: Is this a case of nervous chills, of hectic fever, of ague, or of syphilitic or urethral fever; or is somewhere internal abscess formation going on? The thermometer is applied, and, as all instruments of precision, its record reveals the truth. While the skin apparently is cold, the temperature rises to 105°, later to 106° and 107°, and during the stage of sweating the thermometer shows a decline of the temperature of 2° every ten minutes, till it has reached about 98° or $\frac{1}{2}°$ below normal. Herewith the diagnosis is decided; this temperature record, this rapid, great rise and decline, is only found in intermittent fever, due to malaria, and in no other dis-

* The Physician's Clinical Record, for Hospital and Private Practice, with Memoranda for Examining Patients, Temperature Charts, etc., etc. Philadelphia: D. G. Brinton, 115 South Seventh Street. 1881.

ease. The indication for quinine is given, and the fears of the patient and his relations can be at once dispelled by a favorable prognosis.

A lady has a common bronchitis. After this has progressed as usually, for four days (I describe a case as it actually occurred in my practice, and I may mention here that all the instances given are taken from actual life), she suddenly complains of severe pain in the lower part of her abdomen, which is tender. There is no tympanitis, no wiry pulse, no Hippocratic face, no vomiting, and the pain disappears again after the application of leeches and the appearance of the menses. But the thermometer recorded a temperature of 105°, and whenever this happens suddenly in connection with the abdominal symptoms this patient had, even if they should leave again, this increase of bodily heat denotes mischief, denotes a lurking, fatal peritonitis. So it was in this case. Though the symptoms were by no means grave after the cessation of pain and tenderness, forty-eight hours later sudden collapse set in, and death took place almost before I reached the patient, who lived only a ten minutes' ride away from me. The post-mortem revealed what I had told her relatives: the peritoneal lining of an old pelvic abscess, which had been encapsuled for years, inflamed, in consequence of the same exposure to cold which had given origin to the bronchitis. Then the abscess "pointed" and burst into the peritoneal cavity, which fatal accident caused the sudden rise of the patient's temperature. As after the application of the leeches and the appearance of the menses the symptoms all left, and the case had by no means a fatal aspect, I would have made myself ridiculous and injured my reputation, by a favorable prognosis, from the giving of which only the thermometer saved me, its record of 105° warning me of the approaching dissolution.

A young man, who for some days has been complaining of general lassitude, pain in his limbs and his head, and who perhaps had slight epistaxis also, is feverish one evening, and sends for the physician, who does not know what is wrong, but who employs the thermometer, and finds a temperature, say of 99°. The next morning the patient feels better; his temperature is 98½°. Being a careful man, the doctor leaves the thermometer with the patient, giving full directions to have the latter's temperature taken the same night. On his visit the day after, the doctor sees, from the self-registering instrument, that the patient's temperature had been 100° the night before, while it is perhaps 99° at his morning visit. Keeping a record of the case, the doctor observes, say by the seventh day, that his patient's temperature had been as follows every night (decreasing every morning from ½° to 1° from the temperature of the night before): first night, 99°; second, 100°; third, 101°; fourth, 102°; fifth, 103°; sixth, 104°; seventh, 104°. From this fact alone, even if diarrhœa, tympanites, and eruption have not made their appearance as yet, or only moderately so, the physician knows that he has a case of typhoid fever before him, as only this disease gives the temperature record described. The temperature will now be stationary, *i. e.*, in a moderate case, 104° at night, 103½° in the morning, till the thirteenth or fourteenth day, when it will decline about as follows: —

14th	day, morning,	102½°	; night,	103½°.
15th	" "	101½°	; "	103 °.
16th	" "	101 °	; "	102½°.
17th	" "	99½°	; "	102 °.
18th	" "	99 °	; "	101 °.
19th	" "	99 °	; "	100 °.
20th	" "	98½°	; "	99 °.
21st	" "	98 °	; "	98½°.

i. e., the temperature will fall in the morning sometimes 1° to 1½°, or even 2°, but creep up at night to near the same height as the night before, until the twenty-first day, when it has reached the normal, or below it. The following points are of importance regarding diagnosis and prognosis. If after the twenty-first day the temperature continues high, say 103° or 104°, it always denotes one of three things: either a longer continuance of the fever, or a relapse, or mischief within the chest, mostly tubercular deposits. If from the eleventh to the nineteenth day the temperature suddenly declines 4° to 6°, hemorrhage from the bowels, due to corroding of a blood vessel, is sure to follow within six to twelve hours. Oozing hemorrhages are generally accompanied or succeeded by a fall of the temperature of 1° to 2°, mostly immediately after the setting in of the hemorrhage. In typhoid fever a temperature of 103° indicates a mild case; of 104°, a moderately severe; 105°, a grave; 106°, a very doubtful prognosis; and 107° a fatal case. If, during the second week, the morning and evening temperature record are alike, if no decline of at least ½° in the morning takes place, the prognosis is the very worst possible. Such cases end invariably with death, and the same holds good of any other disease.

Just as typhoid fever is characterized by this slow creeping up of the temperature in the first week, its continuance at the height reached during the second week, and its ups and downs

in the third week, so typhus has its peculiar temperature record. Here the temperature reaches its height, 104° to 105°, within twenty-four or thirty-six hours; latest, however, by the third day. Then it continues at that height, with slight morning remissions of about ½°, till the eleventh or thirteenth day, when it falls to the normal just as rapidly as it rose, generally within twenty-four or thirty-six hours, a sweat or a long sleep—a crisis—ushering in the favorable termination. Wherever this temperature record exists it invariably means typhus.

A child is suddenly taken ill with a chill, vomiting, hot skin and a very rapid pulse. The physician is called immediately, and the thermometer records 105°, or anywhere up from this even to 110° and 112°. This always denotes scarlet fever, as there is no other disease of childhood where such a high temperature is developed with such a rapidity. Usually the thermometer indicates 105° to 107°, and from this fact alone, even without the sore throat, and ere the eruption has made its appearance, the diagnosis of scarlatina can be made.

Perhaps, without any premonitory symptoms, a person is seized with a chill, followed by rapid breathing, a dull pain in the chest, cough, high fever, and a comparatively slow pulse. If the thermometer indicates a temperature of 104° or 105°, while the pulse does not beat over 110 a minute, but the respiration is rapid, the diagnosis of acute, croupous, or lobar pneumonia, will always be accurate. There does not exist any other disease where a rapid breathing and such a high temperature are connected with so slow a pulse; or, in other words, where the number of respirations, degrees of temperature, and pulse beats, do not correspond with each other. Often the frequency of the pulse will not be increased at all, or only by a few beats, and it is not rare to find cases of acute pneumonia with a pulse rate of 84 to 90. The fact is well established, that if the pulse exceeds 120 beats in the minute, the case will certainly end fatally. If in a case of bronchitis the breathing suddenly becomes more difficult and the temperature rises to 103° or 104°, it is an indication of catarrhal pneumonia having set in. If in a case of chronic pneumonia, or at that time of acute pneumonia when resolution should begin, the same sudden rise of temperature takes place, it denotes breaking down of the lung tissue. Should, in a case of pleuritic effusion, the temperature suddenly ascend to about 104°, then fall during the following sweating about 2½°, and a similar rise and decline happen daily at almost the same hour, we know that the effusion of serum has changed into one of pus, that the case has become one of empyema, while a similar temperature record accompanies galloping phthisis and the hectic fever of common tubercular consumption. In all cases of suddenly developing severe inflammations of internal organs, or of breaking down of their tissue, or of internal formation of pus, the thermometer will reveal to us the lurking danger; without its recording a high temperature, the apparently grave symptoms lose immediately their perilous aspect. A hysterical female, suffering, for instance, from acute articular rheumatism, may suddenly complain of intense headache and be wandering in her mind; or she may have a severe pain in her chest, be breathing with difficulty, and the heart beating irregularly; but if the thermometer does not indicate a sudden rise of temperature in either case, the complication of cerebral rheumatism on the one hand, and of endocarditis on the other, may safely be excluded.

Suppose a physician is called to a lady, suffering from intense abdominal tenderness and pain, and vomiting. Peritonitis seems to be threatening, but no matter, how, and how long and carefully applied, the thermometer does not register more than 98½°. What does this denote? That this is one of the protean forms of hysteria simulating peritonitis, where the thermometer alone can tell the truth; assafœtida, valerian, and such remedies, will soon remove the apparently grave illness.

A man, during the heat of the summer months, suddenly drops down, unconscious. Is it apoplexy or sunstroke? In the former, the temperature sinks below the normal, generally to 97°, but may fall to 95°, and what is important to know, if, after creeping up, it should again decline, then such fall indicates that more blood is oozing out, that another hemorrhage is still more compressing the brain; while in a fully developed case of sunstroke the thermometer will never record less than 107° or 108°. And as in apoplexy the renewed fall of the temperature generally means death, so in sunstroke, a gradual decline to the normal (but here, for reasons mentioned above, better tested in the rectum), indicates returning consciousness and probable safety.

In cases of apoplexy, local inflammation, abscess or tumor of the brain, the seat of the lesion can often be detected by the use of the surface thermometer, which will indicate an increase of temperature of 1° to 4° over the diseased part. In hemiplegia the affected side shows, usually, a small decline of temperature, as compared with

the healthy side, excepting lesions of the thalami, where frequently a remarkable increase of temperature is observed. In paralysis, connected with a morbid condition of the anterior cornua, and in cases where the blood supply to a part has been cut off, therefore, in all cases of decided trophic disturbance, the temperature of the implicated limb will often be from 4° to 10°, and more, below the normal. I remember the case of a lady whose left arm felt numb, was the seat of severe shooting pains, and could not be raised by the patient. The case puzzled me very much; the lady complained also of a tingling sensation, and the arm had a bluish white color, but was as yet neither swollen nor emaciated. I could not feel the radial pulse on that arm, but the patient informed me that since childhood she knew of this anomaly of the course of the artery. I felt the brachial artery beating, but very weakly. Sensation was diminished, electro-muscular contractility normal. The surface thermometer recorded only 85°, while the temperature of the right arm (the thermometer being applied to each arm, on the inner side of the biceps) was 99°. The blood supply was here evidently disturbed, and the cause of all the symptoms. A few months later an aneurism of the subclavian artery became plainly visible, and proved the correctness of the diagnosis.

There are many occasions, when a clinical thermometer, or a surface thermometer, gives us valuable information; and, in fact, sufficient observations have now been made to enable us to state of almost every disease its own peculiar temperature record. I selected a few only, to show the great value of this instrument to the practicing physician, be he living in city or country. The thermometer should not be considered an instrument, as the æsthesiometer or dynamometer, which are mainly made use of by specialists, and in colleges, for demonstration only, and for which other means can easily be substituted: no, the thermometer should form part of the physician's armory, as the stethoscope, the speculum, or the forceps do. Besides, if permitted, I would give every physician the advice to keep and *use* in *every* case of illness every modern mode of investigation or treatment. How often has it happened, that the fact alone of the consulting physician taking out his thermometer, or stethoscope, which the attending doctor had not thought necessary to employ in that case, gave to the first reputation, and caused the people to talk about what kind of operations the consultant had performed, and what a wonderful man he was; how he inquired after the urine, and analyzed it chemically and with the microscope, finding its specific gravity with the urometer; how he listened to the heart with the stethoscope, percussed the chest with a hammer and plexímeter; how he took the temperature with a self-registering thermometer, tested the strength with the dynamometer, and sensation with the æsthesiometer; tried electro-muscular contractility with the Faradic battery; and with the galvanic brush, electro-cutaneous sensibility, etc., etc. Certainly it is not this reason which should induce every physician to employ every and all known means of investigation and treatment to make other persons acquainted with them! No, it is the duty the physician owes to his patient which should stimulate him to try all means modern science has put at his disposition. How many a physician has never used a hypodermic syringe, and how frequently did Dr. X. try to remove a colicky pain, or to cause sleep in delirium tremens, which his more careful and shrewder colleague, Dr. Z., when called in after Dr. X.'s means had failed, stopped within a minute or two in the one, and induced as rapidly in the second case, by one hypodermic injection of morphia.

We hope to have achieved with the foregoing at least this result; persuaded some physicians who had not been regularly using a thermometer to do so now, given them the information necessary to make them familiar with its employment, and stimulated further inquiry.

Hospital Reports.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

CLINICAL SERVICE OF WM. THOMSON, M.D.
Professor of Ophthalmology.
Reported by H. F. Hansell, A.M., M.D.

Four Cases of Traumatic Sympathetic Ophthalmia

Case 1.—Richard Ward, aged fifty-five. First presented himself at the clinic July, 1880. Three months earlier received a blow in the left eye from a small stone, while working in a mine, and six weeks afterward the right became inflamed. On the injured eye was a cicatrix extending from upper and outer section backward over ciliary body. Double iritis, with posterior synechiæ. Ordered atropia sulph. gr. iv to ℥j, several times a day, after bathing the eyes with hot water. Both eyes improved somewhat under this treatment. Iridectomy was proposed, but on account of the excessively hot weather, was postponed until fall. In the fall he went, by mistake, to Wills Hospital, where an iridectomy was performed on the right eye, March 25th, 1881. Returned to Jefferson Hospital with little more than light perception in either eye. Both irides

bound fast to cornea and lens capsule; anterior chambers almost completely annihilated, and pupils clogged up with lymph. Iridectomy upward and inward, by Dr. Levis, followed by improved vision laterally. One week later an iridectomy on the other eye, followed by about the same result. On May 17th went home, nearly blind, for the new pupils had become occluded. October 17th returned; right, indistinct light perception, and left but little better. Partial cataract diagnosticated in both eyes. Iridectomy of left, by Prof. Thomson, downward and inward, with the effect of greatly improving the vision.

Case. 2.—Richard Black, aged twenty-five; admitted to house October 1, 1881, with following history: Fifteen years before, left eye was struck with piece of coal, followed by gradual loss of sight, accompanied, however, by no inflammatory symptoms, except for brief period after injury, until two years ago became absolutely blind, losing even light perception. One month before admission right was burnt by hot iron. On admission, left cornea clear. Traumatic iridectomy and cataract. T–2. Right, slight scar on cornea. Vision $=\frac{20}{LXX}$. Nerve injected and with indistinct borders. T. normal. Slightly sensitive over ciliary body, under duboisia right was tested and vision improved to $\frac{20}{XXX}$ by + 1.5. October 13th, left enucleated by Prof. Thomson. On second day vision in right began to improve, until, when he left the hospital, ten days after the enucleation, it had reached the normal acuity.

Case 3.—Alfred Darnley, aged sixty-three; struck in right eye eight years before coming to clinic. Severe pain and inflammation followed the blow, and some weeks later same symptoms developed in left. Lens had been extracted in right; iridectomy upward. Left, iridectomy downward. Vision on admission, right $\frac{20}{CC}$, left $\frac{20}{LXX}$. Ordered atropine one week. Returned with vision = right $\frac{6}{CC}$; left $\frac{20}{XL}$; vision in right brought to $\frac{20}{XL}$ by correcting for the aphakia and traumatic astigmatism. Left could not be improved with a glass. The above corrective he has worn for several months, to his complete satisfaction.

Case 4.—Sarah Garrity, aged nine. Presented herself October 28th. Was struck on left five years before, with an oyster shell. Vision completely lost. Three months ago right became sympathetically inflamed in its anterior part, and *one month* later left was enucleated. Since then vision in right has constantly decreased, until now she can only count fingers at two feet, and then only when held before window or other means of illumination.

Sympathetic ophthalmia holds a place in the domain of eye surgery second in importance to none. In this affection the sight of one eye is not alone to be considered, as in cases of cataract, occlusion of the pupil, corneal opacities, etc., but the total and irrevocable blindness of the patient. Cases of injury of the eyes are not infrequent. Indeed, by those who practice in the cities, or in the neighborhood of large mills, or foundries, or chemical works, they are constantly met with. How important, then, is their early diagnosis and correct treatment. The disease often develops from the slightest and most unexpected causes, *e. g.*, iridectomy or cataract extraction operation, and it behooves every surgeon treating a case of traumatism of the eye to be constantly on the watch for signs of sympathetic disease, and at the very first indication of *irritation* in the sound eye, to be prepared to operate, for after the stage of irritation has passed and *inflammation* taken its place, it is too late, and blindness is the result. Too much emphasis cannot be laid upon this principle. If any error must be made, let it be a too early enucleation rather than too late, and the accusations of conscience which will surely follow an opportunity of saving sight lost through culpable carelessness or inexcusable ignorance will be avoided.

But how does sympathetic ophthalmia make itself known, and by what symptoms is the surgeon to recognize it? Let us consider, then, its principal symptoms, as illustrated in the above cases.

The Ciliary Body.—Under this term I include the ciliary muscle in both its longitudinal and circular fibres; the ligamentum pectinatum, the zone of Zinn and the iris. The last is not generally classified as part of the ciliary body, but as it participates in the disease under consideration at almost the same time, and in the same manner, for clearness sake it shall be described as a part.

In Cases 1, 3 and 4, the ciliary body played the most important part in the sympathetic disease. In all, the iris was bound down fast to the anterior capsule and the pupil occluded by the products of the inflammation. The evident disease here, then, was plastic iritis, and as sympathy was the cause, we have every right to infer that there was also a plastic inflammation of the whole ciliary body, that the identity of the muscle was lost in the mass of exudation and that the function of that part of the eye was abolished. Microscopical examination of eyes sympathetically destroyed has shown that plastic cyclitis and plastic iritis have been the processes which have taken place in the ciliary body.

At the London International Medical Congress, August, 1881, Prof. Brailey said: "The uveitis which is so strikingly manifest in the well marked and severe cases of this disease presents certain definite pathological characters by which it can be distinguished histologically from other forms of inflammation. These characters, though they differ a little at different parts of the uveal tract, are nearly always recognizable in both eyes; though in the sympathizing eye the disease often, as is well known, begins as an iritis serosa with accompaning keratitis punctata, yet here also the peculiar characters of sympathetic ophthalmitis usually become visible at a later stage. The disease is not transmitted from one eye to the other by the passage of *structural change* along either optic or ciliary nerve."

How soon does this inflammation develop after the receipt of the injury? In the above cases the interval was different in each. In the first, six months; in the third, "some weeks"; and in the fourth, almost five years. Much depends upon the nature and severity of the injury and the part of the eye involved. If, for instance, a foreign body, such as a piece of iron, which would undergo chemical decomposition, were

lodged in the ciliary body, the initial inflammation would be more severe and the sympathetic inflammation sooner supervene than if the body were not capable of becoming chemically decomposed and were lodged outside of the ciliary body; or, again, if the substance inflicting the injury expended its force on the cornea, with only secondary involvement of the ciliary region, the second eye would suffer at a later period than if the ciliary body were primarily wounded. So that each case is a law unto itself, and we must be guided in our prognosis and treatment by, first, the constitution of the patient, age, habits, etc.; second, the character of the material causing the wound; and third, the position of the wound and the structure implicated.

The Optic Nerve.—The second case illustrates the second variety of sympathetic inflammation, in which the brunt of the inflammation is borne in the secondarily affected eye by the optic nerve and retina. The ciliary body, however, was not free, as was shown by the sensitiveness on pressure over the ciliary muscle. The patient complained of photophobia and *the gradual deterioration of vision.* On inspection no signs of inflammation could be detected in the anterior half of the eye; cornea clear, except slight opacity from the burn; iris responsive to light and mydriatics; no discoloration, no adhesions, either to cornea or lens capsule; no cataract, no loss of accommodation, no vitreous opacities. Then it may well be asked what was there to indicate that the eye was suffering from "sympathy" with its fellow. First, the optic disc was hyperæmic, its edges were obscured; the lamina cribrosa was invisible; the veins and arteries filled to their utmost capacity; and second, the complaint of the patient that his sight was gradually failing. The result of the enucleation clearly proved the diagnosis to have been correct. Before operation the vision was, by the aid of a hypermetropic glass, a little better than one-half. Ten days afterward, by same glass, vision was improved to normal, or $\frac{20}{xx}$, and the photophobia had disappeared. The period of incubation, if I may be allowed the term, was very long, nearly fifteen years, and, in this, differing in another essential particular from the three other cases.

Thus we see the symptoms and signs of sympathetic ophthalmia differ according to the localization of the disease, and may be classified under two heads:—

1. Anterior. Sensitiveness over ciliary body, particularly the superior portion; gradual failure of accommodation or early presbyopia; iritis and its consequences.

2. Posterior. Optic nerve hyperæmia, neuritis, neuro-retinitis, retino-choroiditis, hyalitis.

The two most conspicuous complaints of the patient are pain, gradual loss of sight.

At one time it was the almost unanimous opinion of ophthalmologists that the sympathetic influence was conveyed by the optic nerve; later the optic nerve theory was abandoned and the ciliary nerves accused of doing all the mischief. But now the two conflicting theories have met on a common ground, and it is believed that the disease is transmitted by both the optic and the ciliary nerves, or sometimes by one, sometimes by the other.

On this subject, Prof. Snellen addressed the Ophthalmological Section of the International Medical Congress, held in London, August, 1881, and suggested—

1. The explanation of sympathetic ophthalmia as a reflex irritation of the ciliary nerves, is not sufficient—

2. As a clue to further research, the hypothesis recommends itself, that sympathetic ophthalmia is to be regarded as a metastatic specific inflammation, in which special parasitical inflammatory elements are conveyed over to the choroid of the sympathizing eye through the dilated lymph paths.

In conclusion, I quote from Mauthner* his views in relation to the time in which sympathetic inflammation is developed, and his four strongly emphasized rules as to the proper time for operation.

"It is an important question, how long a time must elapse until the condition of irritation advancing along the nerve tracts reaches the second eye. Let it be understood at first that it is not possible to state the *latest* time for the development of the disease.

"In one eye destroyed through traumatism, the possibility of its influence on the second persists not only during the time when the first is painful, but even when a foreign body has remained innocuous in the interior of the eye for an indefinitely long time, may be finally called forth. It can, further, in a phthisical bulbus, which, on account of absence of every symptom of irritation appears a perfectly harmless neighbor, from unknown causes, or through formation of bony plaques in its interior, give origin to new painfulness, and thus open a posthumous source of irritation; and finally, there is not the slightest doubt that the germ of a sympathetic inflammation can lie dormant in a *painless* eyeball an undeterminable length of time. Indeed, the literature contains records of cases in which the sympathetic inflammation has developed only after periods of ten, twenty, and even fifty years. Much more important is it to decide the *earliest* time. In this respect it appears to us there is a relation between the length of time and the cause. *A priori*, we cannot measure the time. We have no sure means of knowing how much time must elapse before the diseased condition in the ciliary and optic nerves is transmitted to the opposite side, and although the early appearance of neuro-retinitis in the *wounded* eye is proven, we are still ignorant as regards the ciliary nerve, how long it continues before the same would place that eye in the necessary condition of irritation. *A priori* we must believe that the sympathetic neuro-retinitis must develop in a shorter time than the sympathetic cyclitis, since the tract over which the inflammation must travel is much greater in the latter than in the former. Yet we cannot say that experience corresponds with this expectation. As a rule, one month to six weeks is the interval between the primary and induced inflammation."

Finally, the observations in respect to the ope-

* *Vorträge aus dem gesammt gebiete der Augenheilkunde.*

ration: "It *may* be undertaken as a prophylaxis; it *must* in stages of irritation; it *must not* in iritis serosa and plastica; it *can* (if the sympathizing eye is entirely blind, and not in a condition of active irritation) in irido-cyclitis plastica."

Accepting Mauthner as authority, we learn that enucleation is forbidden after the development of iritis serosa and plastica. What, then, shall be the treatment in that stage? Whatever is possible to be done will be accomplished by an energetic medicinal course; mercury in small doses, carried to ptyalism; rest in bed; mydriatics; leeches; hot water bathing; exclusion of light, and the best hygienic surroundings.

Cirrhosis of the Liver in Children.

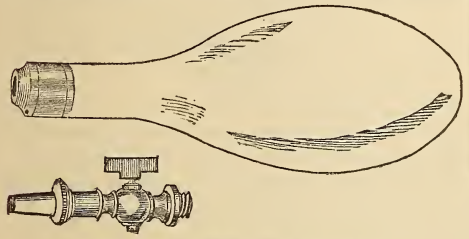
At a recent meeting of the Pathological Society of London (reported in the *British Medical Journal*) Dr. Pye Smith presented a specimen of cirrhosis of the liver which was not the ordinary hobnailed, nor the syphilitic, nor the rare form of cirrhosis due to adhesive inflammation of the portal canals, nor was it a case of so-called hypertrophic cirrhosis. A remarkable corresponding change was found in the lung and peritoneum. The patient was a boy, who was thirteen years old at the time of death; he had been ill for three years; he had the ordinary symptoms of chronic pulmonary phthisis, and also ascites and abdominal pain, which were attributed to abdominal phthisis. He died from exhaustion due to diarrhœa. The pleuræ were much thickened, and there was enormous interstitial thickening of the lungs, which contained numerous vomicæ; there was no caseous change in the lungs, or in the lymph glands, or any part of the body. There was evidence of extreme chronic peritonitis; in the pelvis the thickening of the subperitoneal tissue had formed a tumor, which consisted of indurated fat. The liver was scarred by bands of fibrous tissue; on section, irregular patches of congestion bounded by fibrous overgrowth were seen. The colon was in a condition of extensive ulceration. Microscopical examination afforded conclusive evidence of a true interstitial hepatitis. There was no history of any over-indulgence in spirits: there was no indisputable sign of syphilis; and careful questioning of the mother failed to elicit any family history pointing in that direction. Dr. Pye Smith did not think it could be regarded as a case of tubercular disease, for there was no trace of any caseous change, either in the lungs, lymphatic glands, or peritoneum. He thought it an instance of that tendency to a fibroid overgrowth in many of the organs, owing to some unknown cause, which was seen not very uncommonly in adults. Dr. Mahomed, who had seen the patient during life, and had witnessed the necropsy, had been struck by the amount of the cyanosis and its persistence for two years, and had made the diagnosis of chronic bronchitis, with consecutive nutmeg disease of the liver. This specimen gave rise to much interesting discussion on cirrhosis of the liver in children, especially concerning its etiology. It seemed to be the sense of the Society that these cases were the result of a tendency to general fibroid overgrowth in all the organs, due to some unknown cause. Many cases of cirrhosis of the liver have been met with, in which there was no history whatever of syphilis, tuberculosis, or gin drinking.

Wool-Sorters' Disease.

The London *Medical Times and Gazette* says: In his annual report on the health of the Borough of Bradford, for the year 1880, Mr. Harris Butterfield, the Medical Officer of Health for the district, remarks that during that period several cases of disease, known in that locality as "wool-sorter's disease," have occurred, six of which proved fatal. Although, Mr. Butterfield observes, in Bradford and its neighborhood the malady is peculiar to wool-sorters, yet the disease is not confined solely to them, but may affect all persons whose avocations bring them in contact with the tissues of animals infected with the complaint known as splenic fever or anthrax. Butchers, farm laborers, and workers in horsehair, have contracted the disease, and it is probable that many hitherto unsuspected sources of infection exist. What is yet known of the disease as it occurs in the Bradford district is due, Mr. Butterfield continues, to the research and investigation of Dr. Bell. The Sanitary Committee of the town, assisted by delegates from the wool-sorters themselves, have drawn up a code of regulations to be observed in all factories where foreign wool is dealt with, and since the adoption of these rules no case of wool-sorters' disease has occurred in any of the establishments where they are in force. In addition to the precautions agreed to, some firms require the man who steeps the bales to wear a respirator and long gloves. It is still doubtful, Mr. Butterfield thinks, whether the hairs and wools admitted to be noxious are the only dangerous materials. Anthrax, as an epizoötic, is not confined to the animals from which the admittedly dangerous hair is obtained, but is known occasionally to infect all animals. It is not because home and colonial sheep's wool is never infected that sorters engaged solely on this material do not contract wool-sorters' disease, but because the greasy nature of this description of wool prevents the germ bearing particles from floating in the atmosphere.

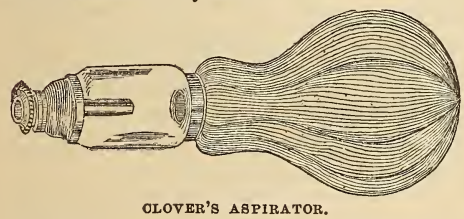
Lithotrity at a Single Sitting.

The London *Lancet* of January 7th, 1882, contains a lecture by the eminent English surgeon, Sir Henry Thompson, whose name has become indissolubly connected with this operation, and from it we quote the salient points. He always commences his lectures on lithotrity by sketching its brief history, which differs so widely from that of lithotomy, which dates back some twenty centuries. The first efforts to crush a stone were made early in the present century, and culminated in the first performance of the operation by Civiale, in 1824. After a considerable interval, during which the operation underwent many modifications, it was proposed by Heurteloup to remove débris on a large scale, and complete the operation at a single sitting, but he did not succeed in this. Before this time, Sir P. Crampton, of Dublin, had invented an apparatus like a large soda water bottle, from which, by means of an exhausting syringe, he removed the air and then applied it to a large silver catheter previously introduced into the bladder. Some twelve or fourteen ounces of water had been injected into the bladder, so that on turning a tap attached to the receiver a powerful rush into it of water and débris took place. This was the first aspirator.



SIR PHILIP CRAMPTON'S ASPIRATOR.

This, however, was found to be too rough in action. Soon afterwards Mr. Clover designed an india-rubber aspirator with a glass cylinder, which answered very well.

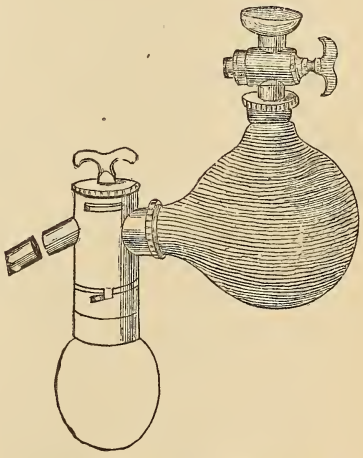


CLOVER'S ASPIRATOR.

In 1878 an important change was proposed by Professor Bigelow. He advised that the stone, however large, and without respect to any collateral considerations, should invariably be removed at one sitting, by the use of more powerful lithotrites, larger evacuating catheters, and a stronger india-rubber bottle than had before been used. Professor Thompson has now resorted to this method in 101 cases, and regards it as a valuable improvement on any method previously employed. In describing the operation, he says that a stouter lithotrite, and one which will bite into a hard stone and *break* it into fragments first, instead of *crushing* it into débris, is preferable. When a stone of medium size has been broken up, and by repeated crushings during some eight or ten minutes is obviously reduced, or nearly so, to débris, the lithotrite should be withdrawn and an evacuating catheter, Nos. 15, 16, to 18, according to previous examination of the urethra, should be introduced into the bladder, when urine and some debris will be expelled. To this catheter the aspirator is next to be applied.

He found the following points essential in determining on the kind of aspirator to be used:—

1. It should be light and small, so as to be easily grasped and managed by one hand.
2. It should have an opening *at the top*, by which it can be filled with water, to which all air accidentally admitted, if any, will arise, and by which it can escape.
3. Its *lower part* should be connected with the evacuating catheter by the shortest route to the bladder, and in such a manner that the aspirator can be detached with ease, and without loss of any contained water in so doing.
4. There should be a trap into which all fragments must fall, and by which they are securely retained. Such an apparatus is shown in the accompanying figure.



SIR HENRY THOMPSON'S ASPIRATOR.

Recent change in the situation of the trap.

The aspirator being attached to the evacuating catheter, alternate pressure and expansion takes place, in obedience to the hand of the operator, who at the same time modifies the position of the catheter according to his judgment on observing the arrival of small fragments and débris in the trap. When much has come over, perhaps only a large piece or two being felt, which evidently cannot issue, the aspirator is removed and a lithotrite introduced, and they are crushed, when the aspirator is again applied and the bladder is completely emptied. This operation must be repeated as long as fragments remain. In from ten to forty minutes a uric acid calculus of considerable size may be thus broken up and removed. He has never consumed more than fifty minutes.

Micrococci in Lupus.

The London *Lancet*, speaking of this subject says:—

The domain of microphytes is fast extending its limits. It is not long since leprosy was declared to be due to their development; syphilis and tuberculosis are believed by many to be largely due to them, and now lupus, an affection which has some undoubted affinities with tubercle, has yielded to Max Schüller, of Griefswald, evidence of micrococci mingled with the cell products. His conclusions are given in a short paper in the *Centralblatt für Chirurgie*, No. 46, a reprint of which is before us. The paper is entitled "Histological Studies on the Micrococci of Lupus," and the author says that, for more than a year he has diligently examined every specimen of lupus he has been able to obtain in the recent state, for these organisms. At first he met with not very satisfactory results, due, he thinks, to the fact that he sought for them in the main mass of cells composing the lupus nodule, and also because of the staining material he used. Improved methods yielded better results. To guard against the intrusion of micrococci from without, the freshly extirpated lupus masses were placed at once either in 2 per cent. aqueous solution of carbolic acid, or treated with 3 per cent. solution of the acid in absolute alcohol. These preparations were then cut by Roy's freezing microtome, either at once or after being left a longer or shorter time in the carbolic solution, which was frequently renewed. The sections were then placed in alcohol and stained by Weigert's method, by 1 per cent. aqueous solution of gentian-violet, and, after sufficient staining mounted in oil of cloves or in glycerine. Only the best and most carefully stained sections were examined, and that under high powers, with concentrated illumination. The smaller nodules lying outside the chief focus in the subcutaneous connective tissue were the best to be examined for micrococci. These nodules, composed of small groups of round cells and a few pale epithelial cells with large round or oval nuclei, were the seat of micrococci granules lying between and around the cell groups. At certain points of the periphery of the nodule short rows of such granules extended into the neighboring connective tissue, sometimes reaching to the next cell mass. The micrococci were not so thickly massed in the tissues as in many acute infectious processes—*e. g.*, in acute infectious osteo-myelitis—but in well-stained preparations they were clearly and sharply defined, and could be detected in the smallest nodules lying far away from the main mass, and even around isolated epithelioid cells, the micrococci radiating from these into the tissue around. In that way stellate masses of micrococci, staining like the cells they surround, come clearly into view, amidst the unstained connective tissue. Probably, these solitary cells, surrounded by micrococci, are the smallest foci of development of the lupus nodule. Owing to the greater accumulation of cells in the completely formed lupus nodules, it is much more difficult to detect the organisms in them, but in very thin sections Schüller found them between the cells and giant cells. In one case of lupus of the lip he found considerable masses of micrococci in the centre of disintegrating nodules. Micrococci can, however, be regularly recognized at the circumference of larger lupus nodules, at places where offshoots of cells spread like roots into the surrounding connective tissue, the extremities of such processes being surrounded by the granules, less closely arranged than in the isolated foci before mentioned. He invariably found these also in the hyperplastic sebaceous glands within the lupus territory, and sometimes in the hair-follicles and around the sweat-glands. He also found them in the walls of the small vessels, surrounded by round and epithelioid cells. In all parts the micrococci form a more or less complete network, by the processes which their masses send out into the neighboring tissue. In a case of ulcerating lupus nasi he found micrococci thickly grouped in the hyperplastic epidermal papillæ around the ulcer. Finally, he has found micrococci in lupus most abundantly in the more recent formations and in the softer tissues, being best seen in portions of luxuriant lupus of the face, lips and nose; more sparsely in old dense lupus foci, which are now and then observed in the skin of the extremities.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——"Diseases of the Ear in Locomotive and other Engineers, Firemen, and Conductors, which may endanger the lives of the traveling public," by Laurence Turnbull, M.D., comes to us in the form of a reprint from the "Transactions of the Medical Society of the State of Pennsylvania." The paper contains many valuable suggestions, and a recommendation that the Legislature be petitioned to pass a law requiring all railroad employés to be examined for their acuteness of hearing, by means of the voice, watch, clock, bells, whistles, etc., before taking charge of a fast train on any railroad in the State of Pennsylvania.

——"Removal of a Cyst of the Pancreas." A portion of a paper read by Dr. N. Bozeman, before the New York Pathological Society. It comes to us in the form of a reprint.

——"Report of Deaths in Providence, Rhode Island, during the year 1881." Compiled by Edwin M. Snow, M.D., Superintendent of Health and City Registrar.

——Godey's Lady's Book for February, is a sparkling number. The steel plate is a beautiful sketch drawn by Darley, representing a scene in "The Cricket on the Hearth," and the novelette, "Cherry Snows," is a thrilling love story from the pen of Carrie Beebe Crocker. The shorter stories, Poems, Recipes, Puzzles, Games, etc., are all first-class, and the Fashion and Work Departments are replete with the very latest designs.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

PHILADELPHIA, PA.

SANITATION AND PUBLIC EDUCATION.

A bill introduced into the Legislature of Ohio by Hon. HARVEY RICE, furnishes food for some remarks on this very important question. School hygiene is the foundation stone of public health.

The young and growing body is profoundly influenced for good or evil by hygienic surroundings. Bad sanitary conditions may so impress the delicate organization of a naturally weak child, as to render him a lifelong invalid, and may so influence a vigorous constitution as materially to lessen his mature powers for private and public work.

It is very gratifying to find our law makers commencing to recognize the great importance of this preventive branch of medicine in connection with public education, and we most sincerely hope and trust that no time will be lost in making this bill a law, and that the good example thus set will meet with a universal following.

The bill under consideration confers upon the Boards of Health of cities of the first and second classes the authority, and makes it their duty, to cause sanitary inspection of the schools in their cities. For this purpose the Health Boards are authorized to secure the services of some physician (not a member of the Board) who shall possess the requisite qualifications, to make all such sanitary inspections, and he shall be allowed the aid of one or more assistant physicians, if necessary. The principal and his assistants shall be remunerated for their labors by the payment of such a sum as the Board shall consider just and reasonable.

The principal physician is compelled to make thorough inspections of the sanitary conditions of all the public schools, investigate any causes that may tend to impair the health of the pupils, and note any requisite hygienic improvements or modifications that may be required. All of which he shall report to the Board of Health quarterly, or oftener, as they may require.

Printed copies of all sanitary regulations approved by the Board must be furnished to the superintendents and teachers of all schools, and it then becomes their duty to faithfully carry them out.

They must also cheerfully, voluntarily, and thoroughly make any suggestions and give all information in their power, that may seem necessary to further his investigations, to the inspecting physician; and furthermore, a penalty of not less than five nor more than fifty dollars fine shall be imposed upon any one who may neglect this provision.

Bravo! this is a big step in the right direction. Every one interested in human welfare and the prevention of disease will owe Mr. RICE a vote of thanks if he succeeds in making a law of his bill.

The West is a wonderfully great country. It is rapidly getting ahead of the East in everything. This new evidence of progress tends to show that even in that development which usually comes only with age and refinement, after the bustle of development of material resources has become settled, the West is ahead of the East. It now becomes the imperative duty

of the legislatures of all our States to follow this wholesome example set them by Ohio.

There is one proposition which we desire to announce in this connection and to have remembered. The history of the world furnishes us abundant evidence of the fact that the very large majority of mankind pay no attention whatever to preventive medicine. When sick they rush off to the doctor, but they absolutely neglect the precautions necessary to prevent sickness. Well, such being the case, it becomes the bounden duty of those who have the power, to force these persons to take care of themselves, and to prevent, as far as possible, the inroads of disease, misery, and death.

We sincerely trust that before long we will have the great pleasure of chronicling the introduction of many such bills into our different legislatures. We shall await anxiously the fate of this one.

THE GERM THEORY AND SOME OF ITS PRACTICAL RESULTS.

The laborious researches of KLEBS, NAUNYN, PASTEUR and others, into the actual cause of the so-called infectious diseases, have brought some practical results already, and promise us daily more. As is well known, minute organisms—micrococci, for instance, in scarlatina and diphtheria; bacilli in typhoid and typhus—have been detected by these investigators as the cause of those maladies. Salicylic and carbolic acid and other disinfecting remedies which destroy these animalculæ would be the proper therapeutic means in such cases, were it not for the fact that they cannot be given in doses large enough to act effectually as physiological antidotes, if we are permitted to use this expression. The animalculæ generally collect in such great quantities in the system they once infect, that very large doses of these remedies are necessary to destroy them. At the same time the reproduction of these low organisms progresses so rapidly, that the means for their destruction have to be employed almost continuously, and not only large, but very frequent doses become necessary, therefore. If the acids above mentioned would be administered internally, as often, and in doses sufficient to fulfill their indication, the remedy would become almost more destructive and dangerous to the system than the infectious animalculæ, the micrococci, or the bacilli. Here we have to thank KLEBS again for an important discovery. He found that the benzoate of sodium or of magnesium destroys the bacilli of typhoid fever, while, even in very large doses, it does not act deleteriously on the system. As the bacilli accumulate in large masses, in this disease, on the mucous membrane of the nose, mouth, pharynx, bronchial tubes and intestinal canal, a strong solution of the remedy mentioned is applied to and brought in direct contact with these parts, and for this purpose it is used in form of injection, mouth wash, gargle, by inhalation, and administered internally, viz: in doses of about twenty grains every two hours, so that altogether—*i.e.* by the different modes of its application—about three hundred and twenty grams of the remedy are daily given to the patient. KLEBS cites the case of a workman in his own laboratory, who had been exposed a great deal to the bacilli, while being occupied with their culturing, and who was attacked by what promised to be a very grave form of enteric fever. But after having been treated for nine days with the benzoate of sodium, and in the manner described, the fever and every other symptom totally left him, and a rather remarkable weakness was the only sequela of which the patient complained for some weeks longer. Considering the well known reliability of KLEBS, the remedy, used as recommended, merits undoubtedly a further trial, and we draw, therefore, the attention of our readers to the same, especially as it can now be procured in our country, from almost any wholesale drug house, and as it is cheaper than either salicylic or crystallized carbolic acid.

Another practical result of the researches connected with the germ-theory is the following: PASTEUR took a drop of blood from a chicken, having died of chicken cholera, or from a sheep which had died of anthrax, and dropped each drop into a small quantity of chicken or mutton tea (prepared like beef tea), the vessels being

closed with a cotton stopper, which allowed entrance of air but no foreign particles that might be contained in the latter. These solutions he exposed for two weeks to the air, when he took one drop of each, and put this into a fresh, pure chicken or mutton tea, which then again was left for about two weeks exposed to the atmosphere. After repeating the same experiment from four to six times, he procured this way, at last, a solution, which, when in the small quantity of a few drops injected under the skin of the respective animal, would hardly produce any local and no constitutional symptoms, but protect the animal as surely against the disease itself, the "diluted" poison of which it was inoculated with, as a successful vaccination with cowpox lymph will protect a human being against variola.

The experiment has lately been tried in public, by the authorities of one department of France, and it proved so successful that the general adoption of this new form of vaccination of animals has been recommended by the government, and begins generally to be practiced in France. As especially chicken cholera is a frequent disease in our country also, it should be the duty of physicians to draw the attention of farmers to the experiments and results gained. And as pleuro-pneumonia of cattle is an infectious disease still prevalent in some parts of our country, and the same can be said of an epidemic disease among swine, it may be well for those who have the opportunity, and live in such localities, to try a similar method in these diseases, and observe if the same results may be obtained.

Here is an opportunity for some member of our profession to make his name well known all over the country. It must not be forgotten, however, that the exposure of the culturing liquid to the air for a certain time is a paramount necessity.

SHOULD SICK MEN BE HUNG?

A case out in Kentucky at the present time makes this a pertinent question. A man convicted of murder was sentenced to death, and the date for his execution fixed. During the interval between his conviction and the date fixed for execution, he was seized with smallpox. At first the Governor of Kentucky (who is a physician) said that this would make no difference, and that the criminal must hang on the day appointed. Subsequently, however, he has granted a respite of nearly a month. We imagine that most persons will approve of this last course of His Excellency. It is revolting to the natural sense of propriety in human nature to think of the hanging of a man whose body is covered and disfigured with the eruption of a loathsome disease like smallpox. Of course, there are two sides to every question, and no doubt there are many who would claim that this man should be hung on the day appointed, whether sick or well.

They would argue that it made no difference to the criminal, when about to be killed, whether he happened to be in good health or not; and they might even claim that such an execution would be doubly effective in dissuading others from becoming murderers, since the idea of hanging a probably dying man would carry a greater impression with it of the sternness and inexorableness of the law.

In this particular case there may have been a special reason for the Governor's leniency, to be found in the fear of disseminating the disease. Such precautions could have been observed, it is true, as would have rendered this danger almost *nil*, but he no doubt thought it better to err on the safe side, and in this view, he should receive the support of the profession. We would take it that such a rule as the following would satisfactorily meet the possibility of more such cases as this one arising.

Whenever a condemned murderer is taken with a contagious disease, he should be reprieved until he is well recovered; but sickness of a non-infectious nature should not interfere with the execution.

Since hanging is justifiable, because by the fear of it would-be murderers are restrained in the execution of their diabolical acts, so the more revolting and more terrible it is made to seem to them, the more deterring influence will it wield.

Notes and Comments.

Flowers in Sleeping Rooms.

Since it is a very common practice, particularly among females, to have flowering plants in their sleeping apartments, and since physicians are often asked whether this practice is injurious to health, the following remarks from the London *Lancet*, seem very timely:—

The public are again warned against the use of flowers in sleeping apartments; and wonderful stories are told of the deleterious effects which have followed their presence in a limited atmosphere respired by invalids. Curiously enough, these appalling "instances" of the evil influences of plants do not for the most part apply to flowers. Nevertheless, we agree that it is safe to banish growing plants and flowers from bedrooms. They can do no good, and they may do some harm, if only by rendering the air of the apartment irritating to the delicate lining membrane of the breath organs. We are not disposed to endorse or accept the charge brought against plants and flowers generally, but it is well to err on the side of prudence; and although it cannot be denied that these embellishments form most pleasing objects for the eye, this advantage must be sacrificed, if, as alleged, they are injurious. There can be no doubt that some plants give off noxious emanations, and others may scatter particles which prove irritating; but are all vegetable growths thus injurious? However, as we have said, it is well to be over-cautious. So flowers and plants must needs be banished, though we part with them with unfeigned reluctance.

Nitrous Oxide as an Anæsthetic During Labor.

The London *Medical Times and Gazette* tells of the recommendation by Dr. Stanislaus Klikowitsch, of nitrous oxide gas during labor. He employs a mixture of four parts to one of pure oxygen, kept and supplied under a sufficient pressure to make its density the same as that of atmospheric air. For obstetric purposes he carries it in an india-rubber bag, which he puts under the pillow of the patient. He claims the following advantages for it: 1st. Its use is free from danger either to mother or child, and it has no effect in prolonging labor. 2d. It does away with pain in all the stages of labor. 3d. Complete anæsthesia can be produced without loss of consciousness, and therefore without diminishing the action of the voluntary muscles. 4th. It does not produce vomiting, nor excitement, nor any bad after effects. 5th. The anæsthesia can be continued throughout labor without any cumulative effect, since, during the intervals of pain, the effects of the preceding inhalations completely disappear. 6. The presence of the medical man is not indispensably necessary for the administration of the anæsthetic. With the editor of the *Times and Gazette*, we must take exceptions to No. 6; it is a very dangerous and reprehensible custom to allow any one not a competent physician to administer any anæsthetic. The only objections urged against the use of nitrous oxide in this connection are its comparative costliness and inconvenience of transportation.

Calcified Adenoma of Scalp.

At a recent meeting of the Pathological Society of London, reported in the *Medical Times and Gazette*, Mr. Eve showed a specimen of this condition. It was a small, firm tumor, lobulated and encapsuled. At first it was thought to be fat. Before microscopic preparations could be made it had to be softened in an acid solution. It was then found to consist of columns of epithelial cells in a fibroid stroma. These columns varied in size; some were branched, some were tortuous. The epithelial cells were small, about the size of those found in the sudoriparous glands, having nuclei. The family history of the young man from whom the tumor was removed was interesting. His father and his father's sister had both suffered from similar tumors. These tumors resembled some which were shown at the International Medical Congress, by M. Malherbe, who described them as calcified epitheliomata of the sebaceous glands. He could not agree to regard them as epithelioma, as there was no infiltration of the surrounding tissues, no leucocytes, and the size of the cells also differed. He thought that they most resembled what English pathologists agree to call adenoma. He also showed sections of a second tumor of the same nature.

Hæmatology.

The London *Lancet* says that Bizzozero and Salvioli have been recently experimenting on the phenomena of blood formation. They endeavored to stimulate the hæmatogenic function of the spleen by copious venesection; with dogs and guinea pigs they succeeded, but failed with rabbits. As a result of their experiments, they conclude that both red and white corpuscles are formed in the spleen; though this view is in opposition to that held by Neumann and Fryer.

Cough of Tuberculosis.

Dr. Whiteway Wilkinson writes to the London *Lancet* that he has frequently been able to afford relief in the early stages of pulmonary tuberculosis by giving the patient, every half hour, alternate doses of sulphate of copper and sulphate of zinc—1.50th of a grain. Without any other drugs the cough gradually gave way.

A New Purgative.

The *Concours Médical* reports that Dr. Rabuteau has experimented with sulpho-phenate and sulpho-cresylate of soda, and has obtained excellent purgative effects with both. A dose of from 20 to 25 grams (ʒv to vj, gr. xv) will induce seven or eight stools in the course of a day. Those salts are eliminated, almost totally, without any change, and their use is advised in cases of fetid diarrhœa.

Detection of Impure Water.

Dr. John Lowe writes to the London *Lancet* about the great danger from impure water to which travelers are exposed, and suggests a practical remedy. If ten or fifteen drops of *Nessler's* test were enclosed in a thin glass capsule and hermetically sealed, the fluid would keep for a length of time. A person about traveling could supply himself with a number of these, and whenever the purity of a water was suspected, one of the capsules should be broken into a wineglass and a spoonful or so of the water added, when all doubt may be set at rest.

Clinical Lessons on Syphilis.

The *Concours Médical* accompanies a notice of the second edition of Fournier's valuable work with remarks, from which we quote:—

Syphilis in all its forms is here treated in a masterly way, and nothing can surpass the boldness and clearness with which the subject is handled. After reading this work, it would seem as if errors of diagnosis were quite impossible. All the accidents attending syphilis, all the consequences directly, or remotely traceable to it, are dwelt upon, and the importance of careful scrutiny into the previous history of the patients is demonstrated.

Sixty pages of this work are devoted, by Prof. Fournier, to the treatment of syphilis. He recommends the use of mercury, notwithstanding all that has been said, of late, regarding the uselessness and dangers of this therapeutic agent. He reviews the different ways of administering mercury, and finally reaches what he terms *his method of successive treatment.* This consists in dividing the treatment into active periods, during which mercury is administered, and into periods of rest, or disencumbrance. According to him, there is nothing excessive in leaving patients under mercurial influence for as long even as two years, including the periods of discontinuance, or rest. The general condition of each syphilitic patient will indicate what auxiliary medication is required, as mercury alone should not be administered. This is but a very brief sketch of this new edition, which contains many valuable additions not to be found in the first.

Contagious Pneumonia.

Dr. R. Jelley, writing to the London *Lancet*, details two cases in which pneumonia seemed to be contagious. He inclines to the belief that there is a contagious form of pneumonia, though he believes it to be very rare. The first case was that of a farmer, aged forty-five. He died of pneumonia. The day before his death, his wife, who had nursed him, was taken with the disease, and she also died. Her sister was confined to bed for one day, with bronchitis.

The second case also occurred in a farmer, who died. His sister, who had been in frequent attendance on him, was taken with pneumonia the day her brother died, but she recovered. All these cases were seen by a consulting physician, as well as by Dr. Jelley, so that there cannot be much doubt about the correctness of the diagnosis. A careful examination failed to disclose any cause for the second case, in each instance, other than contagion.

Boring the Ears.

The London *Lancet*, editorially referring to this subject, very forcibly and very sensibly scouts the idea that boring the ears can have any effect on sore eyes. It reminds us that the only possible influence this operation could have on the eyes would be in so far as it acted as a counter irritant, and since the wounds in the ears heal so rapidly, this argument amounts to nothing; the same, and even better results could be derived from blisters behind the ears.

Treatment of Phagedenic Ulcers.

Dr. Vidal, in *Concours Médical*, recommends:

℞. Vaseline, ʒx
Pyrogallic acid, ʒj. M.

Make into an ointment and apply, morning and evening.

Special Reports.

No. III—INFECTIOUS DISEASES.

Smallpox.

INCUBATION.

M. Marais (*Année Méd. de Caen et Calvados*) had the opportunity of studying, in several cases, the duration of the period of incubation in this disease, and found it from eleven to twelve days. He observed that variola is contagious from the début of the disease, and not alone at the period when desquamation of the pustules is taking place. According to M. Barthélemy (*Thèse de Paris*, 1880), the period of incubation may vary from the ninth to the fifteenth day, and that of invasion from thirty-six hours to twelve days.

A question that has at different times awakened discussion is, whether vaccination during the period of incubation has prevented the complete development of the disease. A case reported by Seymour Sharkey (*Lancet*, Vol. 2, 1877), would seem to decide the question in the negative, for on the eighth day of the vaccinal eruption supervened the classical prodromata of smallpox, followed, after the usual period, by the eruption. The disease ran its usual course, with primary and secondary or suppurative fever, special thermometric curve, etc.

On the other hand, M. Courtes, in the history of an epidemic observed at Adissan (*Thèse de Montpellier*, 1881), states that five persons were vaccinated, or re vaccinated during the period of incubation; one only succumbed, and this was a child, seven years of age, who was vaccinated but two days before the eruption appeared. The other four had the disease lighter, particularly those vaccinated a number of days before the eruption appeared.

THE INITIAL ERUPTIONS OF SMALLPOX.

Mr. Seymour Sharkey (*St. Thomas Hospital Reports*, ix, p. 165) divides the rash into several categories:—

(A) Erythematous rash, subdivided into several varieties: 1. Scarlatiniform rash, which is very frequently observed, and resembles almost absolutely the eruption of scarlet fever on the second day. But the erythema of variola becomes more rapidly generalized than that of scarlet fever, and does not commence on the face and neck, as does this last. Again, it is of a more uniform coloration than the scarlatina eruption, and is not accompanied by the very small elevations, due to the engorgement of the cutaneous papillæ, found in the latter disease. Finally, the inguinal region very frequently presents hemorrhagic effusions, which render the diagnosis certain, when associated with the simple erythema of the trunk. 2. Morbilliform rash is less common than the preceding. As in measles, the spots are separated by intervals of normal skin, but the face is not attacked by the exanthema, which generally disappears suddenly at the moment of the eruption of the smallpox pustules.

These two last erythematous eruptions are generalized, affecting the entire cutaneous surface; those which remain localized are less well known. With Simon, of Hambourg, Mr. Sharkey insists on a form of erythema which remains limited to the extensor aspect of the limbs, for instance, over the olecranon and the patellæ. Our author reports a case of this kind, where there existed, conjointly with variolic pustules of the face, large red patches over the tibiæ, around the knees and along the extensor surface of the forearm.

Sometimes, but not often, this form of localized rash affects exclusively the flexor surfaces, and this is particularly true for the hemorrhagic form. Mr. Sharkey gives a case where the simple erythematous rash, in no way hemorrhagic, presented itself in the armpits, groins, etc., without at all appearing over the extensor surfaces until later, when the smallpox eruption was plainly apparent.

(B) Hemorrhagic rashes. These are the best known. The most frequent, and at the same time, the most benign variety, consists of a punctiform eruption of petechial spots localized in the groins, the armpits, and at the bend of the elbow. Another variety, and of very grave import, has the appearance of a diffused wine-colored eruption, affecting mostly the same parts as the other. Very frequently the scarlatiniform, or the morbilliform rash is associated with these petechial eruptions.

As regards the prognosis to be deduced from the initial eruptions, Mr. Sharkey thinks that the disease is apt to be of greater gravity when the rash is very extensive or dark colored.

TEMPERATURE IN TRUE VARIOLA.

Dr. Frölich, in *Deutsch. Med. Woch.*, *No.* 48, 1880, gives as the result of his researches on this subject, that during the prodromal stage the course of the temperature presents no characteristic features. On the first day the temperature does not differ from that of other diseases which commence with a chill; until the end of the first week it has the same course as in varioloid, scarlatina, pneumonia, and simple recurrent fever.

It is during the second febrile exacerbation

that the temperature becomes characteristic and renders the diagnosis more certain. But it is only when the course of the temperature is considered as a whole, that it offers any pathognomonic proof, its course during the prodromal stage, or that of invasion or suppuration, offering no special characteristics.

HEMORRHAGIC SMALLPOX.

M. Gachon (*Thése de Paris*, 1880), gives several cases of this form of variola, where the patient succumbed before the appearance of any species of eruption.

The symptoms of invasion were unusually severe, the patients then falling into a state of extreme collapse without exaggerated fever, but with ecchymotic spots disseminated over the body, often preceded by a scarlatiniform rash. The conjunctiva was almost always congested, the roof of the palate covered with bloody sugillations: the urine also containing blood. Death supervened after two or three days.

M. Landrieux relates the following facts concerning five Esquimaux (*Soc. Mèdicale des hôpitaux; Union Med.*, Feb. 12th, 1881): They arrived at Paris January 2d, having lost three of their companions during the voyage, two without eruption and the third on the second day of the variolic eruption. After arriving they were vaccinated, on January 5th, and were admitted to the hospital on the 9th. An infant of 14 months already presented the eruption and died on the third day; the four others also succumbed, two during the period of invasion, and two during the period of eruption; these last suffered from a profuse and continued bronchorrhagia, while their urine consisted almost entirely of blood. The most important anatomical alterations, besides those produced by profuse hemorrhage, were the enormous development of the liver, which weighed from four to six pounds, and was in a state of extreme steatosis; the congestion of the kidneys, with considerable augmentation in volume, and fatty granular degeneration of several tubes, and the fatty deposit in the heart, interstitial and not affecting the muscular fibres.

A case of purpura variolosa, reported by Dr. Nixon (*Dublin Jour. of Med. Science*, Oct. 1877) well demonstrates the difficulty in arriving at a diagnosis between purpura hemorrhagica and hemorrhagic smallpox.

A young man, 28 years of age, had, suddenly, several violent chills, without rachialgia or vomiting. On the fourth day a livid, erythematous eruption appeared on the back of the hands and forearms. The eruption soon became generalized, with more marked coloration than is observed in scarlatina. Simultaneously there appeared on the belly and the inferior limbs petechial spots and ecchymoses, but the eruption did not at all affect the face.

On the fifth day hematemesis and hemorrhage from the bowels occurred; and the patient succumbed the same evening. At the autopsy the blood was found black and of extreme fluidity.

The lungs presented the lesions of diffused sanguineous apoplexy. The liver was the seat of fatty degeneration, resembling the state of the organ in steatosis produced by phosphorus. The kidneys were of the normal condition.

M. Renou considers this a case of hemorrhagic variola.

INFLUENCE OF SMALLPOX ON PREGNANCY.

M. Jobard, in a very interesting monograph on this question (*Thèse de Paris*, 1880), admits that miscarriage, exceptional in varioloid, is common in discrete variola (in one case out of two), and is the rule in the confluent and hemorrhagic varieties of the disease. It takes place almost always during the periods of invasion or suppuration.

Abortion is induced: 1st. By the death of the fœtus, resulting from the infection of the mother, or direct variola affecting the product of conception. 2d. From uterine or placental hemorrhage. 3d. From primitive uterine contractions, the least frequent cause.

Abortion may give rise to redoubtable hemorrhage, even in the non-hemorrhagic forms of the disease. Puerperal septicæmia is not to be especially feared.

In cases where miscarriage does not occur the temperature generally remains below 39.5° C.; if it mounts higher there is imminent danger for the fœtus. The author is of opinion that the disease is not invariably communicated to the fœtus in utero, and when contagion does take place it is generally at an advanced period of the malady; in all cases it is proper to vaccinate the child, as if it had not been so nearly exposed to contagion.

Lothar Meyer (*Arch. f. path. An. und Phys.*, p. 43, 1880), expresses a somewhat similar opinion; although the smallpox contagium traverses the placental vessels, the receptivity of the fœtus for the disease is much less marked than that of the newly born child. Again, vaccination is less apt to be successful in the newly born infant than when older, but when the virus is sufficiently active and the operation well done, the results are generally satisfactory. When there is no fever, and the inflammatory areola is absent

after vaccination of the newly born, immunity should be considered incomplete.

NERVOUS PHENOMENA DURING AND CONSECUTIVE TO THE ERUPTION.

The dominating idea of the monograph of M. Barthélemy (*Thèse de Paris*, 1880), is that the variolic virus acts through the intermediary of the infected blood on the nervous centres. This he considers proven by the constant presence of fever, cephalalgia, rachialgia, and the temporary or permanent paralysis which frequently accompanies smallpox, and finally, by the characters of the eruption itself. On the other hand, the toxic nature of the virus is shown by its power of inducing steatosis of the heart, the kidneys, and the liver. The spinal cord and the sympathetic system appear particularly affected, as is proven by the absence of cerebral troubles, or delirium, in the gravest forms of the disease, when there has been no anterior tendency to alcoholism.

M. Saint-Philippe (*Gaz. Méd. de Bordeaux*, No. 44, 1879) notes, in one case, temporary labio-glosso-laryngeal palsy during the period of eruption, followed during the period of suppuration by paraplegia, which very gradually disappeared, as did also the other symptoms of nervous derangement. M. Manissolle (*Thèse de Paris*, 1880) has found that the nervous phenomena consecutive to variola are sometimes of cerebral origin, characterized by delirium, followed by an alteration in the disposition of the patient, feeble memory, general mental dullness. Frequently speech is affected; in some cases there is aphonia. The author also notes ataxy of the upper and lower limbs, with conservation of sensibility. The pathogenesis of these accidents is obscure.

SMALLPOX AND CEREBRO-SPINAL MENINGITIS.

Dr. Grimshaw (Dublin *Jour. of Med. Sci.*, May, 1876) reports a case where the symptoms were those of cerebro-spinal meningitis, where even the diagnosis seemed confirmed by the autopsy. But it was learned, subsequently, that the patient was brought to the hospital from a locality where smallpox was epidemic, and immediately after his death eight patients in the same ward were attacked with the disease. Dr. Grimshaw, *apropos* of this case, insists on the sometimes insurmountable difficulty of diagnosis between malignant black smallpox and cerebro-spinal meningitis. Rachialgia exists in both, and is not always cervical in variola and lumbar in spinal meningitis, as has been asserted; vomiting is not a sufficient differential sign, for it may be wanting. Even the anatomical diagnosis is a matter of discussion, for in the malignant form of meningitis no pus is found in the meninges, but hemorrhagic suffusions are often present. It was for this reason that Stokes put all these malignant fevers under the same generic designation, grave purpuric fever.

LUNG TROUBLES IN VARIOLA.

The pulmonary lesions of variola are studied by M. Breynært (*Thèse de Paris*, 1880); he describes the pustules of the trachea and bronchial tubes, which do not descend to the smaller tubes. He then considers the actual pulmonary alterations, which are, in order of frequency and gravity: 1. Splenization or inflammatory congestion. 2. Spleno-pneumonia. 3. Broncho-pneumonia, with disseminate or confluent points of inflammation. 4. Capillary bronchitis. All of these alterations resemble very much, anatomically and clinically, those of the same kind found in typhoid fever, and have the same causation, which is the adynamic vasomotor paralysis and the blood infection.

M. Joffroy (*Arch. de Physiol. Norm. et Path.*, 1880) asserts that there exists in smallpox a special form of bronchitis, independent of pustulation in the bronchial tubes; this form of bronchitis is frequent, if not constant, during the course of the disease in the adult, and is often complicated with broncho-pneumonia.

ALBUMINURIA IN VARIOLA.

M. Couillaut (*Thèse de Paris*, 1881), founds his deduction on the observation of 116 cases; he found albumen in 42 of these cases, and while it was present in but 5 out of 27 cases of varioloid, in 9 out of 17 cases of confluent smallpox, and 8 out of 14 of the hemorrhagic form, albuminuria was found to exist. Albuminuria of the acute period of the disease is very common, and is observed often in the most benign forms, but is more frequent in grave cases. It lasts generally but two or three days, disappears after the acute disease, and is never the début of renal disease. Albumen is especially apt to appear in the urine at the début of the period of eruption, during the fever of suppuration and when there supervenes any inflammatory complication (pneumonia, pleurisy, orchitis, etc).

The albumen is in small quantity (3 to 5 grains per pint) and is opalescent, hardly ever granular or flaky. The author considers the albuminuria due to temporary superalbuminose, induced by the exaggeration of the organic excreta, under the influence of febrile combustion; it is, however, possible that there exists some temporary alteration of the renal epithelium.

Albuminuria appearing during convalescence is rare; it is symptomatic of acute nephritis, of which it presents all the usual clinical characters (scanty, lactesecent, frothy urine, œdema of the face and limbs, anasarca, visual troubles, sometimes uræmic convulsions).

These cases should not be confounded with simple œdema, without albuminuria, a phenomenon which seems due to vasomotor paralysis, and which is never fatal. Secondary nephritis after variola is of serious prognosis, and may degenerate into Bright's disease.

Correspondence.

Preservation of Cadavers for Anatomical Purposes.

Ed. Med. and Surg. Reporter:—

In your issue of January 21st, in reply to a correspondent who asks for a good embalming injection, you speak of chloride of zinc as a preservative for dead bodies. For the preservation of dead bodies for a period of weeks, or months, as is required in dissecting rooms, there is undoubtedly nothing superior to chloride of zinc, which has the single objection that it decolorizes the tissues. If your correspondent desires a fluid to preserve bodies until burial, such as is required by undertakers, there is nothing better than arsenite of sodium, unless the weather is very warm, when zinc chloride is the best of all. The reason for the preference of arsenical solutions when the body is to be kept but a few days, while being transported, is apparent, when I say that it leaves the tissues of normal color. I have had in my dissecting room arsenical subjects which looked like living men quietly sleeping, so well was the tint of lips and skin preserved. Arsenic will, in cold, winter weather, keep anatomical subjects for a month, or more; but in warm and damp weather it is ineffectual beyond a few days.

The best methods of obtaining the solutions of zinc and arsenic in an economical way may interest some of your readers. I never buy solution of chloride of zinc from a manufacturing chemist, because it is sold at a high figure. It can be made of sufficient purity for anatomical purposes at one-eighth or one-tenth the cost of the prepared solution. Commercial muriatic acid can be bought in quantity for four or five cents a pound, and scrap zinc can be got from plumbers and workers in metal for three or four cents a pound. Two pounds of muriatic acid added to sufficient zinc scraps to make a *neutral* solution will give enough chloride of zinc for preserving an ordinary size subject. The strong solution so obtained will measure about one and a half pints, and must be diluted with about four quarts of water, and then strained carefully, that no small fragments may remain to choke the arterioles during injection. The cost, therefore, of home-made chloride of zinc solution for one subject will not exceed ten or twelve cents; while that of a similar quantity of the manufactured solution will be about one dollar.

Recently there has been extensively offered for sale in Philadelphia, a disinfectant, which is a solution of zinc chloride, obtained from galvanizing works. This contains a little iron, but, if made neutral by the addition of a few pieces of zinc, or soda, to take up the excess of acid, answers as well as the other zinc chloride, and costs practically the same, viz., ten or fifteen cents per subject. This I have used almost exclusively, in my school, for three years.

Solution of arsenite of sodium is made by putting one pound of arsenious acid (cost varying from five to ten cents, according to quantity purchased), into two quarts of water, and adding slowly, while the mixture is boiling, about a pound of sal soda (costing one or two cents). The soda should be added with care, in small amounts, because it is desirable to add only sufficient to combine with the arsenic; as soon as the insoluble arsenic is dissolved it is evident that the whole has become arsenite of sodium. Any additional soda would only render the solution alkaline, which might be detrimental to the integrity of the coats of the vessels.

So much for the preparation of these preservative fluids, which are cheap, effective, and in themselves odorless. The zinc will keep a subject which is exposed to the air fit for dissection two or three months, when it will mummify and become too hard and dry for service. Arsenic in this climate will not keep the cadaver perfectly for more than a week or two, except in cold winter weather. In summer it is valueless for practical anatomical work.

These two solutions are preferable to glycerine, alcohol, Wickersheimer's fluid, chloral, etc., chiefly because of their cheapness. Wickersheimer's fluid is objectionable, because of its offensive odor and its expensiveness.

When injecting the zinc solution, the first few syringefuls should be quite weak, because a strong solution hardens the small arteries, which are contracted after death, and therefore the preservative fluid does not reach the periphery of the cadaver; hence the skin and subcutaneous cellular tissues are imperfectly preserved. This will be shown in a few days by the puffing up of the integument by subcutaneous gas, and by the separation of the epidermis from the true skin.

It is unfortunate that we possess no injecting material which is cheap and effective, which has the power of destroying the cadaveric poison, which permits muscles and other pink tissues to retain their color, and which, at the same time, leaves the arteries so distensible that the subsequent reddened plaster injection can flow to the remote arterial distribution.

John B. Roberts, M.D.

Phila., Jan. 28th, 1882.

Albuminuria in Pregnancy.

Ed. Med. and Surg. Reporter:—

In your issue of January 7th, I notice an article copied from the *Canadian Journal of Medical Science*, on the "Indications for the Use of Morphine in Puerperal Eclampsia," by Dr. L.

McFarlane. The writer has evidently had to do with a few cases of convulsions in lying-in women, resulting from nervous prostration, accompanied with anæmia and hysteria, where opium and free stimulation were indicated, and straightway rushes into print with the surprising declaration that this is the true pathology, not alone of these few cases which he has so treated, but of *all* cases of puerperal convulsions. It is the old story, "generalization from insufficient data." The "albuminuria" theory on this subject, promulgated some years ago over the water, carried away whole hecatombs of victims, and that its utter falsity and stupidity were not demonstrated sooner is a standing reproach to the medical profession. Again it appears, in another form, equally objectionable and equally stupid. It is not surprising, in this age of crude and undigested thought in all departments of human learning, that some one should write such a piece as this, but that it should be selected and dignified by a place in your excellent journal is incomprehensible to me.

The mischievous tendency of such literature is so palpable to the thoughtful medical man as to need no demonstration. When will we learn, and not forget the fact, that the producing cause of convulsions in pregnant or lying in women is not a constant quantity? A constant cause implies a constant remedy, and the logical sequence is a "wild goose chase" after that will o'-the-wisp called a specific. Admit a constant cause, and a constant pathology, and the doctrine of specifics is made out, and a physician is no longer needed. Packages of medicine neatly labeled from the shelves of the druggist will answer every purpose, and our "occupation is gone." Most unfortunately there are, and always will be, insurmountable obstacles in the way of this most happy consummation.

Diversity of personal qualities in the patients would of themselves preclude the idea of treating all cases alike, even if the pathology were always the same. Our nomenclature for different forms of disease is as faulty as it well can be. Take this one in question, "puerperal convulsion." It describes a symptom, but gives not the slightest hint at the cause, or the real diseased condition. As well say "puerperal headache," "backache," "stomachache." Neither of the expressions is an intelligent answer to the all important question: What is the matter with the patient?

The truth is, there are at least three widely different pathological conditions which produce convulsions in lying in and pregnant women. 1st. A true cerebral hyperæmia, very closely allied to that which is present in apoplexy, resulting, if not promptly relieved, in effusion, coma, and death. 2d. Anæmia, added to a nervous and excitable organization, by some very properly called the "hysterical variety." 3d. Those who have uræmia from true inflammation, or granular degeneration of the kidney. This last variety is admitted to exist, but it is quite probable that careful investigation would show that the puerperal state has little or nothing to do with their production.

Albuminous urine in pregnant women means nothing at all, practically, of itself. More than one-half of them have it, after the fifth month, and nothing serious ever comes of it.

It is certainly true, at least in this part of the country, that cerebral congestion is the all important factor in the production of this frightful malady. Dr. McFarlane would have us give opium in these cases. Who would be stupid enough to follow his directions? The necessity is so strong and urgent, and the indications so plain, for the use of the lancet, that I am at a loss for a word to express it. Certainly in my own pretty wide experience with such cases, I have never seen any therapeutic agent, under any circumstances, produce more happy results. It must be used with an "eye single" to the effect upon the circulation, without regard to the quantity of blood taken, to be followed, as soon as the patient can swallow, by a mercurial purgative, or a drastic cathartic of some description. The only patient I have seen die of this terrible disease was one of the victims of the "albuminuria" theory. It is not a pleasant recollection. The plainest possible indications for depletion were neglected and thrown aside for an *abstraction.*

On Typho-Malarial Fever, so Called.

Ed. Med. and Surg. Reporter:—

In a communication in the Reporter of Jan. 21st, 1882, headed "Some Points in Malarial Fever," by J. W. Hickman, M.D., Delta, Pa., he says he remarked to an intelligent physician that malarial fevers were this year of unusually intense type; and the reply he received was, that they no doubt had associated with them a typhoid element. As I made such a remark to Dr. Hickman, and as I believe there is a disease which we cannot call by any other name, I have concluded to give some reasons for my belief. I also remarked that Dr. Woodward had written a small work, and described the disease among the first. His work I never saw, nor his retraction of it; but I have talked with Dr. Woodward on the subject, as he and I were attached to the same division during the Peninsular campaign, I having charge of Kearney's Division Hospital, where I had ample opportunities to study the malarial fevers of that region. We did not have as well marked cases of typho-malarial fever there, however, as we have here in our malarial districts. Prof. Dickson, however, held the same view before Dr. Woodward wrote his work on the chief complicating diseases of the United States armies. And we also have such an able teacher and author as Prof. Flint *scattering such opinions among the people.* In Flint's practice, page 839, he says, "Typho-malarial fever is caused by the combined action of malaria and the special cause of typhoid fever. He also says, practitioners in malarious situations have been accustomed to say that remittent became converted into typhoid fever. This mode of expression is not accurate. There is not a metamorphosis of the one disease into the other, but a combination of both diseases, the phenomena of the one or the other disease predominating in different cases."

I have met with many cases this season which

commenced with a chill every afternoon, followed by a temperature of 104 and 105° in the evening. The next morning it would be normal. And with all the anti-malarial remedies used the chills would continue for ten days or more, when they would gradually cease, and the fever become continuous, with all the symptoms of typhoid fever, even the rose colored spots, bronchial trouble, tympanites and diarrhœa. Some cases would start as remittents, and end with all the typhoid symptoms. To call such cases pernicious intermittents or remittents is nonsense. When a case of intermittent or remittent fever does not yield to full doses of quinia, repeated for three or four days, you generally have the typhoid combination. I confess I never give the doses recommended by Dr. Hickman, 20 to 30 grains, three to four times daily; his maximum dose would be 30 grains, four times daily, or an ounce in four days. Such doses I consider uncalled for and dangerous. Nor would I, as a rule, give his minimum dose, 20 grains, three times daily, for I have seen unpleasant symptoms produced with less doses. I know several medical men of over a quarter of a century experience in malarial districts, and who are neighboring practitioners of mine, who treat and recognize typho-malarial fever, and they are neither knaves nor ignoramuses. W. F. Smith, M.D.

Airville, Pa.

News and Miscellany.

Pharmaceutical Preparations.

LIQUID PANCREOPEPSINE.

The value of pancreatin as a digestant has been amply indicated by Dr. Dobell. Messrs. Warner & Co. have combined it with pepsin and lactic and muriatic acids in the preparation named above, and thus furnish the several aids to digestion required in the stomach and upper bowel. Their compound solution is of a delicate straw color, clear, agreeable to the palate, and very well adapted for atonic conditions of the upper digestive tract.

HERCULES MALT WINE.

This is a new and palatable form of malt extract with the addition of a small but fixed quantity of alcohol, and prepared especially for dietetic and medicinal use. We can commend it as entirely pure, and well adapted for use where a light tonic beverage is indicated. It is manufactured at the Prospect Brewery, corner of Eleventh and Oxford streets, Philadelphia, Pa.

Emma Abbott and Vaccination.

A daily paper has the following about Emma Abbott, the songstress. Some weeks ago she was singing in Chicago, and becoming alarmed at the prevalence of smallpox, determined to be vaccinated. But where? She thought it would be outrageous to disfigure her arm with a scab and scar. Finally, the left leg, above the knee, was decided upon. She was cautioned to exercise the limb as little as possible, which advice, of course, she neglected. Finally, one evening, in St. Louis, she appeared in the mad scene from Lucia, and was so enthusiastically received that all caution was thrown aside, and she exerted herself to the utmost. *Result.*—She was laid up with a badly inflamed thigh and had two doctors attending her. *Moral.*—Do not be so foolishly vain as to be vaccinated where judgment says the operation should not be performed. The arm is decidedly the best place, and it should always be done there.

Longevity Among the Irish.

It is a noteworthy fact that remarkable instances of longevity are to be found among the Irish; and it is particularly striking when we notice that these cases occur mostly among the lower classes, who are submitted to many hardships. It would seem to be a telling argument against excessive luxury, and in favor of some hardships and rough usage as a factor in the promotion of longevity. From an exchange, we note that during the quarter ending the 30th of September last, the deaths of eleven person 100 years of age, or upward, were reported. One man, who died at the age of 101, was able to work on his farm up to within a week of his death. A woman, who died at the age of 100, was able to go about the day before her death, her senses being perfect; while another woman, who died at 103 years of age, had lived for eighty years in a cabin on the summit of the highest of the Burrew mountains.

The Progress of Medicine.

The *Lancet* notices a recent article in the *Westminster Review*, commenting on the progress of medicine in recent years. Among other prominent points, it says: "Medicine though not strictly a science itself, yet rests upon several sciences, and is truly scientific in its processes and results. The writer clearly demonstrated that the claim of medicine to be considered truly scientific is not unfounded, and that its progress in recent times is but the first fruits of a harvest that promises to be gathered in not slowly, and the value of which to individuals and to the race will be incalculable.

Sanitary Convention.

A sanitary convention will be held at Ann Arbor, Michigan, under the auspices of the State Board of Health, on February 28th and March 1st, 1882. There will also, at the same time, be held an exhibition of sanitary apparatus. Further information may be obtained by addressing the secretary, V. C. Vaughan, M.D., Ann Arbor, Michigan.

Pennsylvania State Medical Society.

All persons who have papers which they desire to read before the Pennsylvania State Medical Society, at its next meeting, are requested to forward the title of the same, with their address, to Dr. William Varian, Titusville, Penna.

How to Give a Savage Dyspepsia.

An English physician with whom Sydney Smith was always in a controversial state, accepted a professional call to Australia in its early savage days. When taking leave of him the wit said, "Good-bye, Doctor; you have never failed to disagree with me, and I believe you will disagree with the savage who eats you."

Items.

—A family living near Corinth, Kentucky, were recently poisoned (five of them it is thought fatally), by eating corn bread supposed to contain arsenic.

—It is stated by Dr. Billings (U. S. A.) that 100,000 people die annually in the United States, from preventable diseases and avoidable accidents.

—Mr. Erasmus Wilson, President of the Royal College of Surgeons, England, has received the honor of knighthood, in consideration of his numerous gifts to charities, etc.

—False ipecacuanha is distinguishable from the pure drug by being more branched, by its dirty white color, and by the absence of the annular rings present in the *genuine* article.

—A young lady, who for some time complained of pain in her shoulder, as though a pin was sticking her, was recently operated upon, when a needle found imbedded in the flesh was removed.

—It is reported from Erie, Pennsylvania, that thirteen persons in a boarding house were poisoned by gas from a coal stove not properly closed. When found, they were insensible, but recovered.

—Our venerable friend, Mrs. Partington, says that "Ike has an irrigating disease: Charlotte russe broke out all over him, and if he hadn't worn the Injun beads as an omelette it would doubtless have calumniated fatally."

—Statistics show that Paterson, N. J., in proportion to its size, has more one-eyed men than any other city in the United States, except Pittsburgh. Nine tenths of those thus afflicted are workers in iron and steel, and have been struck in the eye with the metal chippings.

—One day recently, Dr. Augustus F. Müller, of Germantown (a suburb of Philadelphia), while driving along the turnpike, was startled by the appearance of a masked man, who grasped the horse's bridle and leveling a pistol at the doctor's head, demanded that he should "shell out." The doctor gave his pocketbook, containing ten dollars, to the highwayman, who thanked him, and expressing regrets for his unceremonious way of asking a loan, disappeared. The matter was subsequently reported to the police.

—A prize, of the value of £100, offered by the Equitable Life Assurance Society of the United States, for the best essay on "Life Assurance," has been awarded to T. M. Dolan, F.R.C.S. Edin., of Halifax, Yorks.

Does it not seem a pity that with all the talent and energy to be found in this country, a foreigner took this American prize away from us, or does it argue that we set so high a value on our talent as not to consider such a trifling prize worth striving for?

—A man accused of fraud assumed hydrophobia, and was with difficulty conveyed to a hospital on a stretcher. He subsequently admitted that he had been malingering. He was subjected to galvanic shocks, but stood them so well that, as a final test, one of the medical operators said, "Take him away; we'll try the 'big' battery to-morrow." This hint of what was yet to come, it is said, proved a little too much for the prisoner's endurance, and he ultimately confessed that he had been simulating madness.

OBITUARY NOTICES.

SIR ROBERT CHRISTISON, M.D., F.R.S.

This distinguished physician died recently, in London. He was born July 18th, 1797. In 1819 he graduated in medicine at the University of Edinburgh. He then went to Paris and studied toxicology under Orfila. Returning to Edinburgh in 1822, he began the practice of medicine, and was soon afterwards appointed Professor of Medical Jurisprudence in the University. Ten years later he was promoted to the Chair of Materia Medica. He was a witness as an expert in poisons in the celebrated Palmer trial in London, in 1856. In 1866 he received the degree of D.C.L. from Oxford University, and was created a Baronet in the year 1871. He received the degree of LL.D. from his own university in 1872. Sir Robert twice held the position of President of the Royal College of Physicians, Edinburgh, and at the time of his death was Ordinary Physician to the Queen, for Scotland. He resigned the Chair of Materia Medica in April, 1877. He contributed numerous articles to medical journals in both London and Edinburgh, and was the author of several books. One of his works, entitled *A Treatise on Poisons*, is recognized as the standard work on the subject.

MARRIAGES.

HARRIS—BAKER.—In Marlton, N. J., Jan. 15th, by the Rev. Isaac Cook, William H. Harris, M.D., and Mrs. Elizabeth C. Baker, all of Evesham township, Burlington county, N. J.

JOHNSON—STRUBLE.—On January 18th, by Rev. R. B. Foresman, Dr. Levi W. Johnson, of Morristown, N. J., and Lizzie Struble, of Hunt's Mills, N. J.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

Lecture.

GONORRHŒA IN THE MALE; ITS NATURE, CAUSES, AND TREATMENT.

Delivered in the Medico-Chirurgical College of Philadelphia,

BY CHARLES I. MITCHELL, PH.D., M.D.,

Professor of Chemistry, Sanitary Science and Venereal Diseases.

Gentlemen:—The subject to which I propose to call your attention this morning is gonorrhœa. Gonorrhœa is a local disease, confined to the urethra in the male, and the vagina and urethra in the female. We more rarely have it, by mediate contagion, affecting the mucous membrane of the eye and lids, the conjunctiva, where its action, producing gonorrhœal ophthalmia, is most disastrous.

Gonorrhœa is caused by the direct contact of the part with an infecting material. This material may be the purulent discharge of another gonorrhœa, the acrid uterine and vaginal discharge of an active uterine catarrh, or the partially decomposed and irritating flow of closing menstruation. Still more rarely it may be produced by the deposition of virulent purulent matter from a non-venereal source, such as a purulent ophthalmia, by the use of chemical irritants, or by an abnormal and irritating condition of the urine.

There are at the present day two theories regarding the origin of gonorrhœa. One claims that true or specific urethritis can only be produced by a special venereal poison, the gonorrhœal pus from another person suffering with the same disease. The other argues that there is no special venereal poison, and that the disease can be produced by any irritating agent. At the present time the weight of evidence seems to be in favor of the non-specific theory. Experiments have shown that a most violent inflammation can be produced in a healthy urethra by the deposition of purulent matter from a non-venereal source, and that this inflammation is in no respect yet known different from that produced by direct venereal contagion. Prof. Otis, of New York, has introduced into the urethra of a healthy individual the pus taken from the eye of a child suffering from acute ophthalmia, and in less than a week a virulent gonorrhœa was produced. A case of my own will also illustrate the fact that a slight irritating discharge from the uterus can cause a violent gonorrhœa. A young man, well known to me, came under my care for an attack of clap. The disease was in its acute stage, attended with all the symptoms of great œdema, chordee, painful micturition, purulent discharge, etc., etc. The attack proved to be one of the most virulent I had ever seen. I caused him to bring to my office the person from whom he had derived his trouble, but who I had some reason to believe was not likely to have a specific gonorrhœa. I made a most careful examination of uterus, vagina and urethra, with the result of finding only a slight congestion of the uterine neck, and no specific or other form of inflammation. She informed me, moreover, that intercourse had taken place before menstruation had entirely ceased. It so happened that a friend of my patient also visited this young lady, a night or two subsequent to my patient's encounter, and suffered no bad results whatever. I had every reason to believe that the facts had not been misrepresented, and that this was a case of gonor-

rhœa not caused by specific poison. I am treating a female patient for active uterine endo-cervicitis, and also have under my care her husband, who is suffering from a gonorrhœa contracted from this source. Another argument against the specific nature of gonorrhœa is found in the fact that in public asylums, or institutions, where a number of young girls live together, an attack of catarrhal vulvitis originating in one person may be communicated from one to another, until nearly all the members of the community become infected, and present a series of symptoms not to be distinguished from a specific disease. Ricord says, "women *frequently* give gonorrhœa without having it; he should have said *most frequently*. For one case of gonorrhœa resulting from contagion, there are at least three in which contagion, strictly speaking, plays no part. The opinion of many of our most prominent gynæcologists is in accord with these conclusions. In view of these facts you must be very careful in passing judgment upon the virtue of a woman, especially with such odds in favor of her innocence.

Gonorrhœa can also be produced by ignorant "self treatment." A man exposes himself to a suspicious connection; fearing that he may become infected, he tries to prevent the disease from appearing, and accordingly goes to the drug store and requests the clerk to put him up a twenty-five cent bottle of injection, "something strong, that will take it out of his system." Or some kind friend gives him a prescription which is very good, as he was cured by its use. The kind friend may have suffered from a gleet, or chronic urethritis, and when our transgressor uses on a normal or but slightly inflamed urethra the injection intended for a chronic case, you need not be surprised to find him suffering from the disease he so ardently desired to prevent. I have been called upon a number of times to cure an active clap originating in this manner, from nothing but a little mucous discharge from the urethra, which, if left to itself, would have disappeared in a few days.

Again, in males who have a stricture of the urethra, or a chronic gleet with granulation, any indiscretion, such as a prolonged "spree," excessive intercourse, or intercourse with a woman suffering from a slight leucorrhœa, may be sufficient to inflame these already weakened parts, and light up on the old site an active attack of gonorrhœa. I cannot refrain here from giving you Ricord's celebrated receipt for catching a clap. "Select some woman of a pale, lymphatic temperament—a blonde is better than a brunette—and the more 'whites' she has the better. Take her out to dine; order oysters first, and don't forget asparagus afterward. Drink often and freely, white wines, champagne, coffee, liqueurs, they are all good. After dinner dance a while, and have your friend dance with you. Get well heated during the evening, and quench your thirst without stint, with beer. At night play your part valiantly; two or three times are not too much; but more would be better. The next morning do not forget to take a prolonged hot bath; moreover, do not omit to take an injection. This programme having been conscientiously f l owed out, if you don't have a clap some good deity must have saved you."

Fournier's statistics are also of much interest in this connection. In making an investigation of the class of women from whom gonorrhœa is derived, he found them to be divided as follows:—

Public prostitutes,	12
Clandestine prostitutes,	44
Kept women; actresses,	138
Shop girls,	126
Domestics,	41
Married women	26
	387

I have found a large proportion of cases in my own practice to be derived from illicit intercourse with married women. I have found also, upon inquiring into the history of these cases, that nearly all of the married women who caused the disease were suffering from some form of uterine disease. This is additional proof, to my mind, of the non-specific nature of gonorrhœa for had it been specific the husband would not have escaped. As it was, being "acclimated," so to speak, he did not experience ill effects. I will first consider the disorder in the male.

The pathological changes which take place in an acute attack of gonorrhœa consist chiefly of a hyperæmia of the mucous membrane, with swelling, pain, and increased cell proliferation. The epithelial cells thus thrown off are imperfectly developed, and consequently readily undergo fatty degeneration and become puriform. The disease travels backward from the meatus, and according to Desormeaux, has by the eighth day involved the anterior half of the urethra, the mucous membrane being reddened, roughened, and devoid of polish, with bare spots like those seen in balanitis when the epithelium has exfoliated. These changes remain the same in the advanced stage, only the lesions involve the deeper portions of the canal, particularly the sinus of the bulb, the membranous and even the prostatic urethra. With the subsidence of the

acute symptoms, the inflammation disappears from the greater portion of the channel, and limits itself to special points, probably the most frequent being those just spoken of. Here granular or fungous elevations form, of a deep red color, and the mucous membrane becomes thickened, and often tough and horny. These patches prolong the gonorrhœa into a gleet, and lead inevitably to stricture.

The prognosis of gonorrhœa is generally good, the disease being self limited, and in ordinary cases without treatment not lasting over six weeks.

The period of incubation of gonorrhœa is from one to six days. The more virulent the disease the sooner the symptoms appear, and the severity of an attack may often be predicted by the duration of the incubation.

The first symptom of gonorrhœa is a slight tickling or pricking sensation at the meatus during micturition. On examination, this is found to be a little more florid than usual, and slightly pouting, and on gentle pressure, one or two drops of a clear, viscid liquid can be made to appear. This is the first stage. It lasts from twelve hours to two or three days, the discharge gradually increasing in quantity, becoming milky in color, and showing under the microscope the presence of pus corpuscles. At the same time the pain in urination becomes more noticeable. The second or acute stage now commences. The discharge becomes quite profuse, thick in consistence, and yellowish, and even slightly greenish, from the presence of blood corpuscles. It also possesses a slight, peculiar, disagreeable odor. The urethra itself is slightly prominent along the under surface of the penis, and is sensitive to pressure. The glans penis is swollen and congested, and the prepuce is often so enlarged and œdematous as to make the head of the penis twice its natural size, and to render it impossible to uncover the glans. The whole penis is in a state of partial erection, much congested, and painfully sensitive. Micturition is now extremely painful. The pain is cutting, burning, and scalding, and is felt along the whole ante-scrotal portion of the urethra, often extending also to the deeper parts. The urine is ejected spasmodically in small jets, the stream being forked and irregular. At this stage of the disease another complication is likely to occur. At night, after the patient has retired to bed, he is troubled with peculiar painful erections; these symptoms have received the name of *chordee*. The genital organs, in consequence of the inflammatory nature of the disease, are in a highly sensitive condition, and are readily excited by voluptuous dreams, a full bladder, or the contact of the bed clothes. He will awake, therefore, with an excessive erection, the penis being bent in the shape of an arch, with the concavity downward. This peculiar condition is caused by the extension of the inflammation from the urethra to the delicate tissues of the corpus spongiosum. Plastic lymph is poured out around the canal, infiltrating the tissues, glueing them together, and rendering them less capable of extension than those of the corpora cavernosa. Hence, the urethra is too short for the latter, now much enlarged by erection, and acordingly the penis is bent downward, the inelastic corpus spongiosum acting like the string of a bow. The suffering attending chordee is very marked.

Hemorrhage from the urethra may occur at this period. It may be produced by a simple erection, but more frequently follows some condition of prolonged excitement, such as a debauch, or sexual excitement. The practice of "breaking the chordee," as it is termed, will frequently produce copious, and even dangerous bleeding. In this, the patient bends the curved penis violently, so as to straighten it, with the result of rupturing more or less of the congested blood vessels. It is a dangerous practice.

Other complications, such as acute cystitis, prostatitis, orchitis, or cowperitis, caused by the inflammation extending to the bladder, prostate, testicles, or Cowper's glands, will be described when I come to speak of the affections of those organs.

The stage of gonorrhœa which I have just described is variable in its duration. As a general rule it lasts from one to three weeks, being much influenced by the habits and constitution of the individual.

The last or subacute stage of gonorrhœa is characterized by the disappearance of all acute symptoms, and a gradual return to a normal state. The discharge becomes less and less purulent and scantier in quantity; the pain on urination disappears, the swelling subsides, and the urine is passed at the usual periods. The duration of this stage is much influenced by treatment; it may be soon cut short, or left to itself, may linger for months.

Gonorrhœa acts differently upon individuals; in some the disease may never be more than subacute, or chronic, in others the acute symptoms may be very severe, and be attended with great constitutional disturbance. Professor Agnew mentions a very interesting case, where, in three days from the commencement of the attack, the constitutional symptoms ran so high as to

finally develop blood poisoning, followed by death.

To be continued.

Communications.

SHOULD BLOOD LETTING BE MORE FREQUENTLY EMPLOYED?

BY THOMAS H. MANLEY, M.D.,
Of New York City.

If one were to solve this question by leaning on modern authors, in either therapeutics or clinical medicine, he should answer emphatically, No! If again asked to give some of the reasons why blood letting, at the present, is ignored, and by many condemned, he would find it more difficult to answer.

Let him first proceed to answer the second question; and to do so satisfactorily, he must first show that disease, in its course and termination, is different to what it has been in ages past, requiring other milder remedies to abort, subdue, or moderate it. Failing to do this, he must show, as a matter of *fact*, that since the lancet and the leech have been laid aside, the death rate has been diminished, and under the administration of drugs *alone*, maladies have taken a milder course; he must prove that especially inflammatory disturbances of the economy have been less mortal than formerly, and that their sequelæ have been less formidable and more curable when met with narcotics, ice-water baths, and the so-called antipyretics, as salicylic acid, quinia, etc. But when statistics, as well as everyday experience, are consulted, it will be found that proof of the affirmative cannot be sustained. The timid and doubtful beginner, to justify his views, says Professor So-and-So doesn't bleed; during my three years' course at an American medical school, I never saw a person, young or old, bled by my instructor, even by the application of the scarificator or leech; a lecture was never given on the subject by the surgeon or teacher of practical medicine; in fact, I supposed the art so dead and obsolete, that a knowledge of it was non-essential.

In such a state of blissful ignorance is our modern medical man when he offers himself to the public; and he will soon be called upon to preserve health, prolong life, and avert death. A noble representative of the medical profession! He may be able to recite Virgil, read Homer, or quote Cicero, but when the time comes in his patient's case that the lancet should be used, or the leech applied, he is at sea. He neither knows *how* or *when* to bleed.

No single agent is known in medicine productive of so much good, when judicious care is exercised, as venesection, or the local abstraction of blood by the leech, scarification, or puncture. An explanation cannot always be rendered as to how it *acts*, either by appealing to physiology or pathology. It is frequently employed empirically, as in cases of hæmoptysis, and other instances.

But pathology—though through it we may sometimes recognize mortal maladies, has it cast a single gleam of light on the treatment of diseases, except those managed by the surgeon? Watson says in his lectures, that "Lænnec's discovery of auscultation and percussion rather retarded and obscured the treatment of those pulmonary affections which it assisted the world to recognize." Pathologists to-day may have a war of words about the identity of diphtheria and croup; the varieties of pneumonia; tubercles as the only exciting cause of tuberculosis, etc. But withal, have they, in any material way, contributed anything toward an improvement in the treatment of those affections?

The same drugs and applications for all pulmonary affections, the inevitable poultice, plenty of opium to force sleep, aconite, veratrum viride, and digitalis. The fact of a man's lung being loaded with an undue quantity of stagnant blood—as it were—pressing up and down against an inflamed pleura, is of no consequence. That the heart is laboring under a terrible strain, to force as much blood through one lung as should normally go through two, is regarded in the same manner. Plenty of digitalis in order to rouse the flagging cardiac muscle. Meet delirium with chloroform, and the removal of the cause that gave it birth is of no moment; *the man must sleep.*

In the primary stages of brain, pulmonary, rheumatic, and abdominal inflammations, blood letting is the sheet anchor. Keep back your poisons and give nature a chance. In cirrhosis of the liver, the overcharged portal system finds a vent through the stomach.

"Sustain the patient," is the cry; "most inflammatory diseases are *self limited.*" The most fallacious and dangerous doctrine ever enunciated. An admission that the medical art is powerless, is a monstrous nuisance.

By sustaining a man in high fever, is generally understood, to cram him with strong solutions of albuminous substances, as milk, and meats; to this is added free stimulation with alcoholic drinks. When every gland in the body is in a state of intense congestion—no single one doing its full duty; when the power of assimilating

food is crippled or destroyed, and the patient lying prostrate, making no expenditure of strength, he is recommended strong food, such as he might, perhaps, loathe in health; and to make matters worse, stimulants are given. When nature, after bravely struggling against the ravages of the fever, threatens to terminate existence, instead of unloading the vessels of a portion of their blood, new stimulants are poured into the man's stomach. The patient sinking is cruelly crammed with so called *nourishment*, which does not nourish, however. Many of those who advise the plan of stuffing, if I may be allowed to use the term, are also believers in the self limitation of disease. No doubt they sometimes limit *life* if they cannot the disease. They can occupy four or five lectures on tissue changes in the kidney, and alterations in the quality and quantity of the urine. But can they, if they try, show us how, by this demonstration of the dead man's kidney, it will in any way enlighten us as to the cure of one afflicted with a similarly diseased organ? Our province is to relieve distress and effect a cure. In attempting to prove how this is always accomplished, one only plunges further into those mysterious labyrynths of nature where, for ages, the earnest efforts of man have failed to penetrate. Hence, I hold that this extensive research in studies of pathology has been at the expense of therapeutics, and consequently at a large sacrifice of human life.

No one can fail to see that many graduates in medicine, in America, are totally unfit to treat a case of violent fever. They may, perhaps, be able to give the diameters and varieties of blood globules, and give the theories of the multiplication and birth of bacteria, but to perform the functions expected of them at the bedside, they are incompetent.

I make this digression, in answer to the question, "how does venesection beneficially act, when judiciously employed?"

When it is decided to bleed, do it early, and continue it till an impression is made on the system. Lay aside your stimulants and narcotics, as well as rich nourishment, till the fever is aborted, or if it exists, till it is abated. Then, when the patient craves it, give demulcents and acidulated drinks, till the temperature of health is restored. Now for nourishment.

The attending physician never saw a man bled; he might drive the lancet into the brachial artery; and then it is not *fashionable* to bleed now-a-days.

Phlebotomy, to be effectual, must be performed *at the onset* of congestion or inflammation, with an unsparing hand, till its operation is perceptible. Of course it is understood that careful judgment must be exercised in selecting cases for which this treatment is appropriate. Why nature often *admonishes* us how indispensable i is. Epistaxis is often the precursor of fever, and when fever exists, at its crisis, and men of long experience and good judgment claim that phthisis is most curable when the lungs bleed moderately. It is maintained that intense congestion and violent fever, in their incipiency, can be better checked and controlled by free depletion with the lancet than with any other known method. It is denied that death is due to prostration, as that term is commonly understood, from want of nourishment, or prolonged exertion; a most illogical and dangerous assertion. More abstraction of blood in febrile diseases, congestion of the brain, lungs, or liver especially; we will then hear less of apoplexies and heart disease. Avoid giving nourishment without having distinctly in view what it is given for. Give medicine, then, with a sparing hand, no matter how much an especial drug is vaunted; bestow more care on therapeutics, the treatment of the sick, and less on morbid anatomy and pathology. It is well known that man can live on one kidney and one lung. It is also a fact, about which there is no dispute, that there is normally an excess in quantity of blood actually needed by the economy, and that primarily the blood is the seat of all diseases.

Cups, dry, or wet, are most conveniently applied on the chest and abdomen. On the chest, their effect is most noticeable when pain exists, as in pleurisy. Sometimes, when "the spool of the breast is down"—coxalgia—many silly people declare the *bone* in its place after the application of a few cups. In abdominal inflammations generally, we must substitute the leech, on account of its extreme sensibility. Cups are much used in spinal congestion and inflammation and occasionally in sciatica.

In closing my remarks on this very important subject, I would repeat, that my aim has been to call attention to the necessity of reviving blood letting; that it has lately been too generally ignored; and to the ignorance of the manner of performing it; and that the timidity of the attendant is due to unpardonable negligence and carelessness of medical teachers.

And it is only reasonable that the most ready measure of reducing its quantity, and restoring it to its natural state, is that which conduces to reëstablish health. Give the glands and emunc-

tories a chance, by rest, to complete the work of restitution. No more, then, of self limitation of disease. The doctrine is pernicious, and leads to the conclusion that relief cannot be had by artificial interference.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

SERVICE OF DR. JAMES H. HUTCHINSON.

Reported by Geo. F. Souwers, M.D.

Mitral Disease following Rheumatism.

Gentlemen:—I propose offering to you for consideration, this morning, two different and yet similar cases. I say that I am to offer two cases, but in reality, I shall be able only to show you the pathological specimens from one of the patients, she having died within a few days of the time of her admission to the wards, and in the interim between two clinic days. In both instances we have had varieties of rheumatism to deal with; in one a free, frank expression of disease, and which, unfortunately, proved too much for the vitality of the patient; the other, a more or less hidden manifestation of the dyscrasia, and one in which, unless you were familiar with such cases, you would be liable to overlook the exciting cause. The clinical history of L. L., the specimens from whose body I show you, was as follows: She was a German; single; and aged sixteen years. She was fairly healthy until she was six years of age (or about ten years ago), at which time she suffered an attack of inflammatory rheumatism; after recovering from this attack, which, by the way, was sustained before emigrating to America, she enjoyed good health until three years ago, when, immediately after her arrival in this country, she had another attack of acute rheumatism, which lasted five weeks; at the time of this last seizure she suffered severely from intense pain in the chest. Since this time she has never been able to work; there has always been present more or less pain in the chest; dyspnœa, which was especially marked upon making any, even the least, exertion. Last July her abdomen and legs commenced to swell, but this condition promptly disappeared under treatment. About one month ago the legs and abdomen again began to swell, and five days ago (I read from the notes taken on her admission, November 2, 1881), this dropsical condition had reached such a degree that blebs had formed on the skin; these ruptured and left superficial ulcerating surfaces. Upon admission to the hospital the patient was found to be cyanosed, the pulse marking 120 beats to the minute, and very weak in character, the respirations, which were short, being 46 to the minute. Legs very œdematous, the serum oozing out through the skin, superficial ulcers being situated all over the inner side of the thighs and legs. Abdomen much distended, percussion dull over the lower part of the abdomen, especially when the patient is placed in the sitting posture, fluctuation being distinctly felt. The hands likewise are œdematous. The apex beat of the heart is more distinctly felt in the sixth interspace, 2½ inches outside of the left nipple, the whole side of the chest heaving with the impulse of the heart; the area of præcordial dulness is very much increased, there being also a marked systolic murmur, which is somewhat musical in character, this sound being heard most distinctly over the apex of the heart; the vessels of the neck, which are very distinct, can be seen to pulsate markedly. The examination of the lungs gives negative results; urine is acid, with a specific gravity of 1.028, albumen being present in very large amount. We will now leave the notes made by the resident physician for a few minutes and study the case and specimens on their own merits. We have here the history of a girl whose father and mother died of typhoid fever, which is not a trouble capable of being inherited, who during their lives were healthy, and none of whose family, with the exception of the child whose case is under consideration, have ever suffered any sickness of any kind. We have here the story of a patient who suffered repeated attacks of inflammatory rheumatism, but between which attacks she did not complain of ever having suffered any particular inconvenience. I think, however, that, unconsciously, she was suffering under a diseased condition which of itself was not sufficient to greatly inconvenience the economy; after a time, however, the heart lesions, which were the consequences of the first attack of rheumatism, made themselves manifest, and to such a degree that when I first saw her she was cyanosed, her expression of countenance being anxious and disturbed, and she was unable to lie down, owing to the great difficulty experienced in obtaining her breath when in the recumbent position; the conjunctivæ were jaundiced, the nails blue, and the whole surface of the body had assumed a darker hue than in health. In health the heart's impulse is detected in the fifth interspace, below and within the nipple, but here the whole of the left side of the chest moved with every motion of the heart, the most distinct impulse being, however, in the sixth interspace and 2½ inches to the left of the nipple, showing that the apex of the heart was about 3 inches to the left of its usual position; to the right of the sternum, and at and above the line of the third rib, an impulse could also readily be felt. The percussion dullness extended very considerably to the right of the sternum, and so high up above and below the usual point that I thought we might have present an effusion into the percardium, but the very great distinctness of the sound of the heart and the impulse in this region, showed that this was not the case. From the wide extent of percussion dullness, coupled with the fact of the feebleness of the impulse, I concluded that we had to deal with a case in which, while there was hypertrophy present, dilatation of the heart was the predominating condition, and that the heart muscle had ceased to be a compensating force in overcoming the mechanical defects in the valves. On auscultation a loud systolic murmur could be heard at the apex of the heart, this sound being somewhat musical in character.

Upon listening at the pulmonary and aortic cartilages the second sound was distinctly heard, so that these valves were evidently healthy. The murmur was always most distinctly heard at the

apex of the heart, and all the sounds of the heart pointed to regurgitation through the mitral valves. This, however, was not the only difficulty present. On examining the urine it was found to be highly albuminous, with a specific gravity of 1.028. The question arose at this point as to whether the kidneys were primarily or secondarily affected; from the specific gravity of the urine, and the fact that, as I show you, the kidneys are simply congested deeply, and do not present the evidences of organic disease, the opinion I expressed during the patient's lifetime, that the kidneys were secondarily involved, is borne out by the post-mortem examination.

Ascites is rather unusual in disease of the heart, or at least it is unusual to so great a degree as was present in this case. The large effusions into the abdominal cavity and into the lax connective tissue of the general system is accounted for by the congestion of the venous circulation, which was superinduced by the heart's defective condition; the whole of the portal circulation being congested, relieved itself by a simple process of leakage into the abdominal cavity, the blood vessels of the rest of the system following suit, the result being the production of so great a degree of dropsy as to seriously incommode the patient, if not, indeed, to endanger her existence. The patient's respiration was so seriously embarrassed by the presence of so large an amount of liquid in the abdominal cavity, that I determined to resort to tapping. I must warn you, however, that in these cases this operation is not entirely free from danger; for where a patient is weak and depressed, as this woman was, the chances are that she will become a great deal weaker under the process; still, if you deem it essential that the operation shall be performed, do it, but watch the patient closely while you are doing it. I drew from my patient fifteen pints of liquid, when, as she showed symptoms of syncope, I desisted and administered stimulants to her; after the operation she was greatly relieved, and rallied somewhat in her general health and condition. Upon her admission she was ordered half an ounce of the mist. Bash. with the infusion of digitalis (℥j) every three hours, together with 30 grains of the compound powder of jalap, the result being the free opening of the bowels and an easier condition of the patient. Upon looking at the lungs we find them healthy. The heart is hypertrophied and dilated somewhat; three fingers can be introduced into the mitral orifice, and from the ease with which they enter, I doubt not that when the organ was first removed from the body four could easily have found an entrance. The left auricle is dilated and its walls thinned. The aortic valves are healthy. The spleen is deeply congested. When she was brought into the ward we had but little hope of benefiting her, even temporarily; we could but temporize, and make her comfortable, which we attempted to do by means of digitalis, Basham's mixture, and stimulants; there was a temporary improvement, which lasted only for a few days, for, as the notes tell us, her cyanosis gradually increased, while the respirations became more shallow and frequent, her dyspnœa becoming so great that she was finally unable to lie down at all. Finally, the aromatic spirits of ammonia, in 30 drop doses, was administered every two hours. I should have added, when describing her general symptoms, that the pulsations of the heart were transmitted to the vessels of the neck, and could there be distinctly seen. The fluid withdrawn from the abdomen when she was tapped was alkaline in reaction, of a specific gravity of 1.009, and consisted of one-third albumen.

Erythema Nodosum from Rheumatism.

The girl I next bring to your notice is suffering from a disease which, if not identical in nature, presents many points of resemblance to that which produced the serious lesions in the case we have just been studying.

While rheumatism is, as a rule, a frank, well expressed disease, yet there are occasionally cases presented to our notice that would seem to belie this characteristic, and this, doubtless, is one of them. Her history is as follows: Eight days ago, she tells us, she took cold; that in consequence she suffered from sore throat, which was of an aggravated form; even now she has some remains of the throat trouble present. At the time that the attack of sore throat made its appearance she also fell a victim to indistinct pains and aches in the limbs. Now all this trouble would seem to have had its origin in the fact that for a number of days before the onset of the disease she had been working in a damp cellar, or underground kitchen. She had at the time more or less fever, and there still remains some elevation of the temperature, the thermometer registering 100°, the respirations being 22, and the pulse 88. Yesterday, there made its appearance, a dark red, nodular eruption, having its seat more especially over the anterior surface of the leg, the skin of which had, in the neighborhood of these spots, an infiltrated appearance. To arrive at a diagnosis of the skin affection, we must take these factors into account; the fact of the patient's having worked (probably, in an overheated condition), in a cold, damp cellar; the fact that she is aware of having taken cold; that fever was present, associated with rheumatic pains. Now, while we know that rheumatism is generally frank and open in its manifestations, we also are aware that it sometimes gives rise to insidious troubles, that, unless we are on our guard, will tax our best efforts to explain and refer to a cause. This erythema nodosum, or dermatitis contusiformis, is a disease in point; while it may occur, perhaps, as an idiopathic state, yet, as a rule, it owes its origin to a rheumatic attack, or to such causes as will ordinarily provoke an attack of this disease in a person subject to it. It is not a very common affection, nor an ordinary complication of rheumatism; it is more important, for this reason, that you should note this case carefully. From this reddened, infiltrated appearance the nodules gradually degenerate, passing progressively through the same stages as a bruise, becoming first black, then blue, and finally fading away through various stages of yellowness, till the diseased condition exhausts itself, and the skin turns to its normal condition.

Bearing in mind the rheumatic nature of this

disease, we should always use in its treatment the remedies which experience has shown us are useful in rheumatism. We, therefore, prescribe, as the fever is not high, twenty grains of acetate of potash, every two hours. In a case accompanied with much fever I should give salicylic acid; but this is unnecessary here. The prognosis is always favorable; the cases tend to get well, when uncomplicated, in a few days, with the treatment I have suggested. You see now how closely you must watch the manifestations of this peculiar poison; how two cases apparently entirely dissimilar, the one a very grave, the other an insignificant trouble, both owe their origin to a common cause, and yet that both will require, to a greater or less degree, the same general treatment, although the temptation is so strong to deal differently with them.

Dysentery.

In closing the hour I shall discuss before you the case of A. G., aged 26 years, a German woman who has been in this country only four weeks; she presents what is, at this time of the year, and in fact what is now, in this city, a rare form of disease, namely, dysentery. The family consists of herself, her husband, and two children. She tells us that while menstruating she caught cold and was seized with a chill, which was followed by pain in the bowels and decided purging, under which latter she rapidly lost strength, the tongue being covered by a brownish-colored fur. The abdomen, upon examination, has a flattened appearance, and upon pressure in the left iliac fossa pain is elicited; this, however, is diffuse. The stools of these patients should always be carefully examined, not only as to their nature, but also as to their number; the mere statements of nurses and friends should not be relied upon in regard to either particular, for their statements, especially as to number, are apt to be colored by their fears and anxieties. It is, therefore, a good plan to make the nurses keep a record of every passage; in this way some idea may be obtained of the progress being made in the treatment of the case. In the case before us thirty-eight movements of the bowels took place within the first twenty-four hours after she came under our care. Now she has but fifteen in the same period of time. The examination of the stools, while not a pleasant duty, is yet a necessary one, for important diagnostic signs are discoverable in them, especially where a case, as the present, occurs in the middle of an epidemic of typhoid fever; the stools, under such circumstances, will oftentimes enable us to recognize at once the disease from which the patient is suffering. The stools of the patient before us were scanty, consisting almost entirely of blood and mucus, with little or no fecal matter. There is no hebetude, no tympany, no rose rash, and no pain in the right iliac fossa, and the patient tells me that before a movement of the bowels she suffers from pain of a griping character, or as we say, from tormina, together with rectal tenesmus. Her tongue does not present the appearance seen in a typhoid fever case in the second week. The temperature was high when she was admitted, running from 100° to 101°, but it has since fallen off; there was a difference of two degrees between the morning and evening observations; the thermometer readings are different from those of typhoid fever in the second week; this is another point in diagnosis. This disease is far more rare than it formerly was; more or less of it was always seen in this hospital at certain seasons of the year, notably so in the fall, when malaria was prevalent in certain sections of the city. The question has been hotly discussed as to the contagiousness of dysentery. I think myself, that under certain circumstances it is highly so. Take, for instance, the present case: not only the mother, but the whole family, are down with the disease; she was the first and most seriously affected. She tells us that the four of them lived in a room together, and the probabilities are that the chamber was not emptied as often as used, and that from the passages thus retained in the room the rest of the family absorbed the poison. I had under my care at the Children's Hospital, eighteen months ago, four children with this disease, and they also were not the only ones of their family affected by it. The father and mother died of it, and three other children were also sufferers from it. From investigations which were made, it became evident that the father and mother had contracted the disease from constant exposure to emanations from the stools, which were allowed to remain for hours in the sick-room, while nursing a son. I cannot doubt but that where a person is exposed constantly to an atmosphere poisoned by the emanations from the stools of a dysenteric patient, he too will fall a victim to the disease, in a more or less aggravated form. The question is one that has been and is being widely discussed, and I can but add my experience to that of others, in order that by comparing notes we may eventually hope to arrive at the true solution of the question.

As to treatment: I did not see this woman till eight or ten days after the début of the disease, consequently the first violence of the symptoms had somewhat subsided, or else I would have treated her somewhat differently from the way I have. I administered to her ℥ ss of castor oil, with gtt. v of laudanum. Now this may seem to many of you strange treatment for a woman who already was having fifteen to thirty stools a day; but when you pause to consider that with them all but very little fecal matter was found, you see the reason of its administration; the result was a copious discharge of fecal matter, followed by a great sense of relief. After this the bowels were left alone, so far as purgatives were concerned, and a sedative astringent was administered, acetate of lead in two grain doses, combined with half a grain of pulv. opii, being given every four hours. Under this treatment she began to mend rapidly, but it is essential when you give this medicine that the patient should be watched carefully, in order that lead poisoning may not be induced by it. With this danger in view, on the third day I changed my prescription to the nitrate of silver, giving the one-third of a grain at a dose, together with one-quarter of a grain of opium ter die. The nitrate of silver is particularly useful in chronic, or sub-chronic dysentery; where the ulcers left by the disease are disposed to cicatrize, it will undoubtedly promote the pro-

cess; but neither it nor the opium must be pushed indefinitely. The silver, after a time, tends to discolor the skin, but there is no danger of this accident occurring if the use of the drug is stopped at the end of from ten to twelve days; by examining the gums daily this danger need never be incurred, for these will show the silver discoloration before the deposits in the skin are noticeable. In treating dysentery, I have very great confidence in injections into the bowels. The pain in this case was complained of as being very low down, just over the sigmoid flexure, and I concluded that benefit would be derived from an injection, at first once a day, and then oftener, of a pint or more of water, holding a little nitrate of silver in solution; as this would by itself tend to increase the peristaltic action, a suppository of opium was introduced into the rectum immediately after the injection. Now we have, in a week, the passages reduced from thirty-eight to fourteen or fifteen a day, the temperature normal, and nearly all febrile symptoms gone. An important point in these cases is the administration of suitable diet; nothing but fluids should be allowed; milk alone, or, if necessary, combined with stimulants, is the best food; beef tea can be used, and when the ulcers are low down, I should not hesitate to permit small pieces of meat cut fine and masticated thoroughly. Keep such a patient absolutely at rest and in bed; make her use the bed pan, and do not allow her to rise for any purpose; this is of the greatest importance, as one of the first and great objects of the treatment is the conservation of strength, so necessary in order to weather the tremendous drain which such frequent passages make upon the system.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

STATED MEETING, FEBRUARY 2D, 1882.

Sponge Tents.

Dr. Albert H. Smith. It is not necessary to dilate upon the necessity of mechanical dilators for the neck of the uterus, both as a means of diagnosis and as an important therapeutic measure.

The original sponge tents were made from a flat piece of sponge, saturated with wax and pressed flat betwen pieces of marble. This form of tent is comparatively useless, as it expands in one direction only. The first suggestion of the present form was, I think, by Dr. Sims, in his work on Uterine Surgery. His method consisted in immersing a conical piece of sponge in a strong mucilage of gum arabic, impaling it upon a wire skewer and winding it tightly with a cord, after which it was hung up to dry, when the cord and skewer were withdrawn and the tent smoothed with sand paper. If the cord was wound on the sponge with sufficient tightness to give the tent useful expanding power, great difficulty was experienced in withdrawing the stylet. I was led to make a few changes in the method, and now employ a cylindrical piece of sponge, which is saturated with water only, and, without any stylet, is wound with a piece of fishing line, to which a six-pound weight is attached; this compresses it thoroughly, and its form is easily given by the fingers during the process of rolling; the surface should be made as smooth as possible, by means of sand paper.

The tent should be of uniform size from end to end. If it is conical, the tent is introduced as far as possible; but only the small part, without much dilating power, enters the internal os, and it is not unfrequently withdrawn unexpanded, while the external os and the cavity of the cervix are widely dilated. The sponge selected should be strong and fine. I have seen tents made from coarse, rotten material, which would break during the extraction, leaving portions within the cavity of the uterus.

The introduction of medicating materials into an internal cavity of the tent is objectionable, as they usually corrode the sponge, and the space and loose winding necessary to allow the removal of the stylet reduce materially the dilating power. The curved shape is useless, as the uterus can be straightened before the insertion of the tent, and less force is needed for the insertion of a straight one.

To prepare the uterus for the introduction of a tent, first use a dilator of soft metal, or a graduated wax bougie, to straighten the cervix and measure the length and calibre of the uterine cavity, noting tortuosities, etc.; then rapidly introduce the largest tent possible, having first coated it with an enameling material, as soap, and immersed it in a box of salicylic acid in fine powder, which is to be rubbed in thoroughly, to form an antiseptic paste over the tent.

A sponge tent thus prepared may be allowed to remain in situ for forty-eight hours without developing any unpleasant odor, unless there is breaking down tissue which may overpower the disinfecting powers of the acid.

For ease in inserting, I have had constructed a peculiar powerful forceps to hold the tent clamped tightly, and enable the operator to pass it rapidly to its position. Hot water injections after the tent is in position will expand the sponge rapidly and fix it in about a minute. If pain follows the insertion, it can be controlled by opium suppositories.

Time of removal: If the tent is removed at the end of twenty-four hours, it will cause hemorrhage, because the spongioles have buried themselves into the cervical tissues, which grasp them tightly, and a forcible extraction will drag away portions of the uterine tissue and leave a raw and absorbing surface. But at the end of forty-eight hours the tent comes away easily, without any bleeding. The contractile power of the uterus still remains at the end of twenty-four hours, and the presence of a finger or application in the cavity of the uterus causes rapid contraction. At the end of forty-eight hours the uterus is paralyzed, all pain has ceased, and local irritability is less. When the tent is removed, wash out the cavity of the uterus with tepid, salicylated water, and, if necessary, introduce a second tent.

Among the advantages of the sponge tent are its slowness of dilatation—not slowness of expan-

sibility. The power of the laminaria tent is greater as a dilator, but it will slip from the uterus as soon as it has ceased expanding, while the sponge tent will remain as long as it is wanted to. The sponge has also a disintegrating power over morbid surfaces. The healthy tissue will contract again, but diseased structure will not contract but will slough off, its vitality being destroyed. The sponge being porous, discharges will pass through it.

The usefulness of the sponge tent is for both exploratory and therapeutic purposes. It causes less pain than the laminaria tent, and after its removal there is less tendency to contraction, and it is thus more satisfactory for exploratory preparation. The sponge has a stimulant effect on the uterine parenchyma, and in cases of chronic metritis and hyperplastic enlargement it will cause a reduction of bulk. In one case, after the prolonged use of internal applications of iodine, nitric acid, etc., the repeated use of sponge tents resulted in a complete restoration to the natural size. In cases of stenosis the laminaria tent may be preferable, and I prefer it to cutting operations or the use of powerful steel dilators. In one case, years ago, I introduced a sponge tent, in my office, and allowed the woman to walk home and keep about her daily duties. The menstrual flow came on two days later, entirely without pain, for the first time in the patient's experience ; the flow escaped through the sponge and the latter was then removed. Conception occurred before the next menstrual period. The sponge tent is also the safest agent for the destruction of granular growths of the endometrium. A patient had been bleeding profusely at every period for three years; supposing a polypus to be the cause, a sponge tent was introduced, to secure dilatation ; a finger was introduced into the uterus but finding no polypus, more tents were passed to the fundus; fungoid growths of the endometrium were broken up by the tents. I was disappointed in my expectations of finding and removing the supposed cause of the hemorrhages, but was agreeably surprised to find the patient remain well after the uterus contracted. Another patient was sent to me from Boston, for diagnosis only. I obtained permission to use a tent for exploratory purposes. I dilated the uterus with the largest sponge tent, passed to the fundus, introduced my finger and found fungosities on the anterior wall, but the means intended for exploration resulted in a cure.

In a case of polypoid pediculated growths, I at once dilated with sponge tents, after the use of the wax bougie ; the finger found a pediculated growth as large as a hen's egg, but the tent had disintegrated it, and it could be removed by the finger without instrumental aid.

Dr. B. F. Baer reported the following case: In September, 1880, I was asked by Dr. Ch. K. Mills to see Mrs. M. K. She was aged thirty-two, and had had six children, the youngest having been born four years previously. The last labor had been tedious, from uterine inertia, and was followed by a smart post-mortem hemorrhage. Since then she had suffered from a recurrence of metrorrhagia about every two weeks, lasting from a week to ten days each time, and very profusely. The blood loss was attended by severe uterine tenesmus. In the intervals between the hemorrhages there was a constant mucous leucorrhœa. She complained of pain in the hypogastrium and back. Her appearance indicated anæmia and loss of flesh.

Physical examination indicated the following condition: The perineum was slightly lacerated and the vagina relaxed. The cervix uteri was large, soft, from congestion, and lacerated bilaterally, with a swollen, everted and abraded mucous membrane. The body of the uterus was hypertrophied and retroverted, with a slight flexion at the junction of the body and neck. At the point of flexion there was such rigidity of the posterior wall, probably from atrophy, that, when the uterus was replaced, it would return to its old position as soon as released. The sound passed three and a half inches, and proved the uterine cavity to be dilated, and its walls soft and rugous. The internal os, the point of flexion, was quite narrow.

This lady had received proper general medical treatment from her brother, who is a prominent physician, and from others, and during the year previous to coming under my care, she had received local treatment, but with no benefit, so far as the metrorrhagia was concerned.

I diagnosticated, as the cause of the hemorrhages, a hypertrophied, granular condition of the endometrium, the result of subinvolution and retroversion of the uterus, with possibly a polypus.

The plan of treatment pursued was absolute rest, vaginal injections of hot water, reposition of the uterus by placing the patient in the knee-chest position, and scarification of the cervix; followed by an application of Churchill's tincture of iodine once every six or seven days. Ergot, and the tincture of nux vomica, with quinia and some other remedies, were administered internally. The constriction at the internal os made it difficult to medicate the cavity of the uterus properly, and it was thought more prudent to await the result of less radical measures. The result, however, was not gratifying, for the hemorrhages continued to recur with as much, if not more, severity than before. I now introduced a laminaria tent and allowed it to remain about twenty hours. I then removed it with some difficulty, for it was grasped firmly by the internal os, the contraction at which point it had failed to fully overcome. The canal was now patulous enough to permit me to pass the dull wire curette, with which I removed, very easily, a large quantity of hyperplastic or granular mucous membrane. But my patient's temperature was up to 100° before I removed the tent, and her general appearance indicated trouble ahead. It is sufficient for my purpose to state that in spite of every effort to combat it, the temperature continued to rise, and the case gave every evidence of septicæmia, with metritis and perimetritis, and went from bad to worse, until death took place, nearly three weeks after the introduction of the tent. Full precautions were taken to guard against septicæmia.

Why did my efforts to benefit this lady end so disastrously? Ought I to have waited, and given a further trial to less dangerous means of treatment? The patient had been in the care of a

competent gentleman for a year before, and he had pursued that plan most faithfully, with no relief, and my own treatment of the case, before I introduced the tent, had continued over a period of two months, and with a like result; the patient was going down hill, and something more had to be done.

Was the result due to the use of the curette? I do not think so, for the material removed was soft and degenerated. It would have been bad practice to have allowed it to remain.

Should I have used a steel dilator instead of a tent? The tent was used for the purpose especially of softening the indurated tissue at the internal os. The steel dilator would not have done that; and it was very desirable that the os should be made patulous by softening of the tissues, so that the body would contract and disgorge the vessels in its walls. The steel dilator would not have fulfilled the indication so well, but it would have been a less dangerous means of dilatation.

Was the operation deferred too long, until, from the loss of blood, the vessels were eager to absorb any fluid which came within their reach, and the blood itself so disabled that it could not purify itself when poisoned? I believe that comes near the truth.

I do not report this case as an argument against the use of tents, but because I believe all such cases should be reported, so that we may not be led to regard dilatation of the cervix as a simple measure, devoid of danger.

This is the only case of death I have had to follow dilatation with the tent. I have never had a case of death to follow dilatation with the steel instrument.

Dr. E. L. Duer described a method of preparing a sponge tent expeditiously. Take a clean sponge, of cylindrical form, dip it into melted wax, or paraffine, and compress it into form as it cools. Tents may be introduced, when speculum and forceps are not at hand, by wrapping the string attached to the tent around the forefinger of the right hand and inserting the thumb nail into the base of the tent. The first and second fingers of the left hand are passed behind the cervix; the tent is then introduced into the os uteri, and the left hand being quickly transferred to the abdomen, counter pressure is made and the tent forced home. Pain following the insertion of a tent is frequently the consequence of pressure upon the fundus, and if the tent be withdrawn one-fourth of an inch the pain will be relieved. The sponge tent is, without doubt, one of the most powerful means for the reduction of uterine hypertrophy.

Dr. Paul F. Mundé agreed with Drs. Smith and Duer, that sponge tents were indicated in uterine hypertrophy and granulations of the endometrium. He has never had any bad results from dilatation of the uterus by mechanical dilators of any form; but he has withdrawn very offensive sponge tents after twenty-four hours' use, and feared danger might be near and wished to avoid it. He can get tupelo tents of any size; they dilate, not too rapidly, but regularly and strongly, and he preferred to use them, as he was afraid of sponge tents.

In a conversation at Richmond, Va., last May, Dr. Smith said that he had views of his own, and thought the sponge tents were unreasonably looked down upon.

Dr. Mundé agreed with Dr. Smith as to the method of application. He always made use of three steps in the insertion of a tent. He placed the patient in Sims' position. The cervix should be exposed properly and seized by a tenaculum; then the tent, being properly held in a strong forceps, is dipped first into a jar of liquefied carbolic acid, then into a jar of vaseline, and then rapidly passed into the previously cleansed uterine cavity; quickly, if the tent be not too large; if there be any point for it to catch upon, it will catch. At the end of twenty-four hours he always removed the tent, and they were pretty nasty sometimes. He always dreads some bad result, but has been fortunate, so far, and has not seen any. He now uses the tupelo tent, and treats it in the same manner that he previously did the sponge tents. It is easily introduced, it becomes fastened in a few minutes, its effects are good; the patient does not complain of much pain; it does not imbibe so much as sponge and does not sink into the uterine tissue as the latter does, but it is not so efficient in reducing the size of the hyperplastic uterus, for there is nothing else so good as sponge for that. After a tent is removed the uterus should be thoroughly cleansed.

In cases where the sponge was successful for the relief of sterility, a tupelo or laminaria tent would probably have done just as well. A sponge tent increases discharge and causes local irritation, and its removal involves loss of epithelium, and for these reasons it is not generally so good for relief of sterility. As the sponge tent is rough, it sticks, and is introduced with great difficulty if it be of large size in proportion to the calibre of the internal os.

It is a maxim, that a sponge tent must not be introduced into a fresh wound, and does not the dilator or bougie cause a fresh wound? The sponge tent is undoubtedly the best for hyperplasia, but all the other indications are filled by the laminaria, or tupelo tents.

He had experienced the same difficulty as Dr. Smith, in the tapering tent, and had, therefore, cut off the small end of the tent. A Molesworth dilator is open to the same objection in some cases, not dilating either os, but expanding largely in the space between; the conical tent does the same thing; blunt sponges are very difficult to insert; the laminaria has dilated in the cavities of the cervix and body of the uterus, with an hour-glass constriction at the internal os, and it was withdrawn with great difficulty. The tupelo tent dilates more equally, and also more slowly: sponge tents are also hard to withdraw, and should be twisted before traction is made.

Dr. Duer suggested twisting ino ne direction only, allowing the grasping instrument to be drawn in by the shortening during twisting, until the tent was entirely loose. On one occasion, a piece of tent broke off and remained inside the uterus, but it was extruded by uterine action, and was found in the vagina the next day.

Dr. J. Cheston Morris had found out the uselessness of conical tents, unless inserted in a reversed position; he prefers the cylindrical form.

The cases of death from sponge tents were probably due to the use of three successive tents at intervals of twenty-four hours; he prefers to allow a tent to remain from forty-eight to seventy-two hours; he has never had any serious results; but in consequence of the tents being disagreeable and troublesome, he now uses Molesworth's dilator, and with great satisfaction; but they are badly made, they leak, and are apt to break under necessary pressure. In one case he burst three dilators before he succeeded in effecting complete dilatation. He agreed in the usefulness of this method of treatment for hyperplastic enlargement, and thinks that in many cases it acts in imitation of a miscarriage; expansion, then contraction, with the aid of ergot, will cure chronic metritis and enlargement. He is now using large soft-rubber stems to effect a similar purpose; they gradually overcome the resistance of the internal os, and expand it. He has never used the tupelo tent. In his opinion, it is far safer to allow a tent to remain two or three days than only one. In removing a tent, push in slightly at first, and then make traction with a curving motion. He thinks the position on the back far easier for introducing a tent than Sims' position. He has introduced tents in the manner described by Dr. Duer, without speculum or forceps.

Dr. Mundé. Where should tents be applied? At the office? What should be done with the patient after the insertion of a tent? It is very reprehensible to introduce a tent unless a patient can be kept in bed for one or two days after the removal of the tent; this is a very important point. He is accustomed to introduce all tents in the Sims position, and through Sims' speculum, and has not succeeded so well on the back, because the tent easily becomes rough if not quickly pushed to its place. He introduces the sound, and frequently the hard stem, on the back, pushing the uterus down over the stem by pressure above the pubes.

Dr. A. H. Smith. Success in the treatment of sterility by means of sponge tents depends upon the relation of the time of insertion to the menstrual period. If used just before the period, it dilates the uterus and expends all its malign influence before the time at which the uterus is expected to receive the impregnated ovum. The tupelo tent fails in fulfilling the indications, as it would not allow the flow to pass through it (unless perforated), and it could not pass beside it, if large enough to be of benefit. He had commenced to use tupelo tents when they were first introduced; he found them very spongy and soft, with slight dilating power, and easily constricted by the internal os; he did not find it to have any advantages over the laminaria or sponge tent; it has great powers of absorption, and had the appearance, when new, of having been used and dried again. ("The tupelo tents are much better made now, are hard, smooth, and have greater power."—*Dr. Mundé*).

Respecting the use of the bougie before inserting a tent: The bougie does not cause a tear or abrasion of the surface. The wax bougies are flexible, pointed and graduated in form; he has never seen bleeding follow their use; he has never used a steel bougie. He considers that there is far less risk than from the use of mechanical dilators, of which he is much afraid.

There is no difficulty in introducing a cylindrical tent, as it dilates uniformly from end to end, and a smaller tent answers the purpose, as the important point is the internal os; that is where the largest amount of tent is needed. He prefers the position on the back, the relation of parts is more natural and the uterus is more easily straightened by pressure on the fundus above the pubis, making introduction easier.

Tents should never be introduced in the office; it is very reckless; the patient should be put to bed and cleansing injections should be used.

The further discussion of mechanical dilators of the uterus was postponed to the meeting of March 2d.

Editorial Department.

Herpes as an Underlying Cause of other Diseases.

Dr. Moré y Bargit, contributes to the *Revista de Ciencias Médicales.* (*October 25th*, 1881), of Barcelona, an interesting article on the above subject, in which he says:—

Many diseases are treated as idiopathic which in reality are only symptomatic of herpes. This diathesis often gives rise to certain functional disturbances, such as asthma; or again, to more or less extensive ulcers in different parts of the body; cases of blennorrhœa which had resisted all treatment have yielded when arsenicals were exhibited, which is an evidence that they originated from some herpetic vice; if need be, such examples might be multiplied.

As regards asthma, he mentions the case of a man fifty years old, who, in 1879, applied to him for treatment. For the past three or four years he had suffered from severe periodic attacks of asthma, which had resisted all usual forms of treatment. The patient was otherwise in good health, strong, and observed no signs of organic lesions of the heart, or lungs.

On being questioned as to whether he had ever noticed any external signs of herpes, he replied that occasionally he had been subject to a *rose-colored eruption* on the inner face of the arms and over the scrotum, but that it was a very long time since he had been thus troubled, and further that this came to him by inheritance from his father.

Upon these indications the administration of arsenicals was deemed judicious, and he was

advised to continue their use, because if they did not effect a cure, they would certainly bring relief. After a time the *rose colored eruptions* again appeared, and since then he has not suffered from asthma.

In cases of ulcer, these are often due to herpetic taint, and their origin reveals itself when they yield to arsenical treatment. With reference to blennorrhœa, the Doctor, about a year ago, met with a chronic case, in a man, which had resisted every form of treatment. The patient stated that prior to the present blennorrhœa, he had suffered from herpes over the genital organs, that this had entirely disappeared when the blennorrhœa showed itself, and that the herpes had caused him great suffering, owing to intense itching of the parts, while it lasted; he believed that the blennorrhœa was due to a suppression of the herpes. Acting on the indications thus furnished by the patient, arsenicals were prescribed, both internally, and in urethral injections, and at the end of ten weeks, he was entirely cured.

Recently a case of catarrhal conjunctivitis, in a woman, was traced to the presence of herpes, and disappeared under arsenical treatment. I might adduce many other examples, "the doctor says," but it will be enough for the present to detail the following case:—

The patient was a girl, twenty-one years old. of rather weak constitution, and sanguineous disposition, but showing no indications of any particular organic lesions. The menses were regular; however, her appetite was poor, and her digestion slow and difficult, although unaccompanied by any intestinal troubles.

I first saw her on the sixth of last February. According to her statements, for the last six years she had been suffering from ulcer of the womb, and from such severe attacks of asthma that, while they lasted, she was obliged to leave her work (dressmaking), and divest herself of almost all her clothing, so great was her difficulty of breathing.

During the summer she derived great benefit from going out of Barcelona; but as soon as she returned to the city her asthma again came on. She had been all that time under the same physician's care; he had treated the asthma with all kinds of powders, pills, etc., and, according to her say, had given her over a hundred hypodermic injections of different remedies, all without effect.

The ulcer from which she suffered was situated on the right of the neck of the womb. It was about the size of a silver half dime, and was the seat of a somewhat thick leucorrhœal discharge. For the last six years caustics and astringents of all sorts, and even the actual cautery, had been applied, without avail. The patient being always accompanied by her mother, I could not question her, although I had some doubts. It however occurred to me to ask the mother if any of the family had ever been subject to herpes. She replied that they all had been more or less thus affected, including her sick daughter, and detailed various circumstances which corroborated this assertion. This left no doubt but that the asthma and ulcer were due to herpetic taint.

I, therefore, determined on submitting the patient to the following arsenical treatment: For the first week she was given, daily, one-sixth of a grain of arseniate of soda; the second week, one-third of a grain, and thus progressively each week, until five-sixths of a grain daily were reached. We then stopped off for a week, and again commenced the treatment afresh. For the topical treatment of the ulcer, I made use of Ferguson's speculum, and every other day applied a solution of alum. The leucorrhœa was thus gradually reduced, the ulcer healed, and everything returned to its normal condition. The patient recovered her appetite and strength, her color was improved, and the attacks of asthma became milder, and less frequent, until finally, in August last, she was entirely cured.

This shows the influence of herpes in a variety of diseases which at first sight may seem idiopathic, but which, upon careful investigation, prove themselves due to other causes.

Linear Rectotomy for Syphilitic Stricture of the Rectum.

The *British Medical Journal* reports the following case which was operated upon by Mr. Berkeley Hill, in the University College Hospital:—

The patient, E. W., a woman, aged 26, was admitted on May 10th, 1881. She stated that up to about three years before her health had been good, but that since then she had never been well. The history of her illness pointed very clearly to the occurrence of syphilitic infection in the spring of 1878. She first experienced some pain about the vulva, followed by a lump in the groin, which broke and discharged. At about the same time she had a sore throat, general eruption of the skin, and falling of hair. Soon after these symptoms, she began to experience pain during defecation, and some small piles appeared; she noticed also that the fæces became smaller, and that she had some difficulty in emptying the bowel. On admission, the patient stated that the bowels were always confined, and that there was much pain and straining at stool; the motions were stained with blood and matter, and there was a constant discharge of blood and matter from the anus. When examined, the margin of the anus was found to be indurated for about two inches. Close to the outlet it was raised in several places into ulcerating nodules; but there were no piles, properly speaking. The gut, for about two inches above the outlet, was uneven and ulcerated, and so much contracted that the finger was clipped as it passed inwards. The stricture terminated at the upper end by a sharp edge, resembling a band; through this the tip of the finger passed.

On May 18th, the patient having been brought under the influence of ether, Mr. Hill introduced one finger into the rectum; he then passed a large curved needle, threaded with silk, through the skin in the middle line just in front of the coccyx, and pushed it on behind the rectum, until it had penetrated to the cellular tissue between the sacrum and wall of the rectum above the indurated part. The point of the needle was then carried into the rectum, the silk thread seized

with forceps, and drawn out through the stricture; the needle was then withdrawn the way it had entered, leaving the silk ligature in its track. To the silk ligature was then attached a strand of wire, and the wire introduced into the track of the needle by pulling on the silk. The two ends of the wire were then attached to an *écraseur*; by tightening the wire the included tissues were divided in the middle line, with very slight hemorrhage. A morphia suppository was introduced and the wound was plugged with dry lint.

On May 25th, a week after the operation, the temperature being then normal, and the patient free from pain, Todd's dilator was introduced, and expanded to three inches in the antero-posterior direction, and two and a quarter inches in the transverse. This expansion of the cicatrizing wound caused very little pain or bleeding. The dilatation was repeated on May 27th and 31st, and on the latter date bougies were ordered to be regularly used.

On June 3d the act of defecation was easy, while the sphincter had regained complete control of the anus.

The patient was discharged on June 4th, seventeen days after the operation. The highest point touched by the temperature was 101.6°; this was on the evening of the day succeeding that of the operation.

This method was chosen in preference to gradual dilatation by bougies, because the latter is so painful, and affords but temporary relief. Anti-syphilitic treatment was ordered to be continued for some time, in order that any new development of the sclerotic tissue might be absorbed.

Treatment of Ozæna.

Dr. Cozzolino, of Naples, has recently written a monograph on this subject. He recommends a pomade as follows:—

℞.	Hydrarg. chlor. mit.,	gr. xxx	
	Sodii benzoat.,	℥ iiiss	
	Sodii salicylat.,	gr. xv	
	Thymoli,	gr. j	
	Iodoformi,	℥j	
	Ung. petrolei,	℥ ss	
	Acidi tannici,	gr. j	
	Rosar. essentiæ,	℥j.	M.

This to be applied locally, after detersive injections, by Weber's nasal douche.

He recommends prudence in the application of mercurials, and attaches particular importance to a general anti-scrofulous treatment.

For ozæna from atrophic rhinitis he recommends benzoic acid, certain mineral waters in douches or in powder, such as the water of Saint Christau, justly extolled before him by Dr. Tillot, and that of Casamicciola, etc.

He is no partisan of the tampons of cotton-wool of Gottstein, and prefers to them medicated bougies of gelatine of a form invented by himself—a conical form and 3, 4, or 5 centimeters in length, adapted to the calibre of the nasal fossæ. The object of these gelatinous bougies is that they may remain upon the diseased surface in order to obtain their full action. They are made up with the following ingredients.

1. *Astringent or Anti-catarrhal Gelatinous Bougies.*—Subnitrate, tannate, and salicylate of bismuth, pure tannic acid, sulphate of zinc, and sulpho-carbolate of zinc.

2. *Emollient or Solvent Gelatines.*—Chloride of sodium, chlorate of potash, chloride of ammonium, neutral alkaline carbonates, employed to dissolve the inspissated secretions in some cases of dry rhinitis.

3. *Modifying or Resolving and Specific Gelatines.*—Preparations of iodine and of mercury, as, for example, iodoform, calomel, or red precipitate. For specific cases, the iodide of sulphur in herpetic lesions, and corrosive sublimate in syphilitic affections.

4. *Anti-fetid or Disinfecting Gelatines.*—Vegetable charcoal, thymol, salicylic acid, and phenol.

The washing ought always to precede the application of the gelatines and the insufflation of medicated powders. The gelatines are applied alternately in each nasal fossa, especially in the evening. In the morning we ought to introduce the bulb of the nasal douche in the opposite nostril to that in which the gelatine had been applied the previous evening.

Temperature in Childbed.

Dr. Napier gives the following conclusions on this subject in the Edinburgh *Medical Journal*, November, 1881:—

1. The average temperature for a few days preceding parturition is 98.5° to 99°: the subsequent heat is modified by the hour of delivery, but to only a small extent. The healthy puerperal range is 2.5°.

2. No temperature over 99° (unless accounted for by individual nervous susceptibility) is normal after four days. The healthy patient may have an *occasional* night temperature of 100° or 101° within the first four or five days, but a continuing, or even a morning or day record like this requires an explanation.

3. Slight causes, *e. g.*, constipation, retention of urine, etc., give a rise to 99°–100.5°, sometimes more.

4. Retention of clots or secundines, 99°–101°, or upwards; 103° at times.

5. Weid has a sudden late temperature of 103 5°, with rapid pulse; the heat falls quickly with the development of the local affection. Other cases of mastitis are mildly febrile for several days.

6. Metritis (endo- and peri-) gives record of 103.5°, with slow pulse.

7. Peritonitis has a single rigor and a sudden early temperature of 104° or upwards; the pulse is wiry. General peritonitis, if severe, 105.5°–106°.

8. Pelvic cellulitis, oöphoritis, parametritis, etc., have a heat of 101°–102.5°; the pulse is weak and irritable. Recurrent rigors mark fresh deposits of pus, and are followed by temporary increased heat, 104.5°.

9. Pyæmia and uterine phlebitis average 103°, perhaps more. Cases in which the veins are rapidly affected are soon 104.5° to 106°, and end speedily. Pyæmia is frequently late in development, 7 to 10 days.

10. Septicæmia varies from 102.5°–107°. The

heat is never less, at least for some period of the twenty-four hours, than 102.5°, if the case is properly established. The temperature is liable to variations, but after the norm has been reached is less so than pyæmia. There is no security from remission till the night temperature is under 100°. Recovery may take place after 106°, but is rare.

11. Mental emotion may show 104° or even 106°, and we may sometimes have in addition symptoms resembling metro-peritonitis. These cases do not persist, and are generally normal in less than forty-eight hours.

12. If the temperature does not rise within ten days from delivery, there is little risk of grave disease, unless from gross imprudence in exposure to cold, or zymotic infection.

13. Although the temperature is moderately low, 100°–101°, so long as the pulse continues 120 or more we are not safe from relapse. No anxiety need be felt so long as the temperature is kept under 102°. However fast the pulse, if the temperature continues low the prognosis is favorable. An evident exception pertains when temperature is low from collapse. If the temperature is persistent at 102°, or frequently recurs to this point, there must be an abnormal organic condition.

14. Temperature should be observed night and morning for the first seven days, and daily for three to seven days after, more especially if any instrumentation has been required for delivery, or if zymotic or epidemic disease prevails. When an abnormal temperature is discovered, it should be reduced to the normal as early as possible by one or other agent. It is of the highest moment to bring it down to 100° and *keep it* there or lower.

Therapeutic Effects of Damiana.

In *Paris Médical*, No. 48, we read that Damiana Turnera Aphrodisiaca is a herbaceous plant belonging to the Portulaca family, and growing in Brazil and on the western coast of Mexico. Its flowers are white, and have the odor of buchu. It is gathered during August, while its stems are covered with an odoriferous gum-resin.

Damiana has for a long time been used among the Mexicans as a tonic; its stems and leaves are made into a decoction, which is taken to restore strength and nerve energy. It is also given in cases of impotency in either sex. It exerts a specially tonic and stimulating effect on the genito-urinary organs of both sexes, and when given in medium doses, acts as an aphrodisiac, an alterative, and a laxative, with a tendency to increasing the urinary secretions and developing sexual desires. In small doses, it appears to have specific tonic effects on all the pelvic organs, and gives increased activity to the secretions. It is also recommended as a nervine.

Damiana, could, therefore, be used as an aphrodisiac in spermatorrhœa, in atrophy of the testicles, and in incontinence of urine; also as a powerful stimulant of the cerebral faculties, and in all accidents attending premature labor, in difficult menstruation, and in the diseases following gestation.

The effects of damiana are quite different from those of strychnine, phosphorus, or cantharides, which are given in small doses, for the purpose of obtaining immediate results. It acts, not as an irritant, but as a stimulant of the brain, and a tonic of the nerve centres governing the urino-genital apparatus, and its use has to be continued for several weeks. Its effects are chiefly noticeable on the sympathetic nerves, and when taken in large doses, it produces a peculiar intoxication, attended with slight pains in the prostatic region. Its good effects on the kidneys, the bladder, and the genital organs, are also manifest.

In doses of a teaspoonful three or four times daily, continued for several days, damiana has a pleasant laxative effect. The fluid extract is generally prescribed; it is combined with equal parts of pure glycerine, or syrup of tolu, or a fruit syrup of some kind. It may also be taken in wine. It is given in doses of thirty to sixty grains, three or four times daily. A solid extract is also prepared, of which the dose is thirty to sixty centigrams, (= gr. iv ss—gr. ix).

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Soluble compressed pellets, a new form of remedies for hypodermic use, and applicable to ophthalmic and general medication. By H. Augustus Wilson, M.D., Ophthalmic and Aural Surgeon to St. Mary's Hospital, and Pathologist to the Presbyterian Hospital, Philadelphia. This little pamphlet comes to us in the form of a reprint from the Transactions of the American Medical Association, 1881.

Dr. Wilson claims the following advantages for this method of preparing drugs:—

1. The convenient size of the pellets.
2. Their immunity from change.
3. Their accuracy of contents and dose.
4. Their certainty and rapidity of action.
5. That they may be used by the mouth.
6. Their adaptability to ophthalmic medication.

——An experimental and clinical inquiry into the etiology and distinctive peculiarities of Traumatic Fever. By B. A. Watson, M.D. This is an extract from the Transactions of the American Medical Association.

——Fifteenth Annual Report of the Columbia Hospital for Women and Lying-In Asylum, for the fiscal year ending June 30th, 1881, comes to us from the Government printing office at Washington.

——Annual Abstract of Ophthalmological Literature. By C. S. Turnbull, M.D. This essay is familiar to our readers, since it is a reprint from the Medical and Surgical Reporter.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,

115 South Seventh Street,

PHILADELPHIA, PA.

SPECIALISM IN MEDICINE.

The position of the specialist and the relation which he ought to hold to the general practitioner, is accurately and concisely set forth in the following communication to the London *Lancet*. "Some specialties seem to have got a firm footing among us, and it would not be fair to deny that, honestly practiced, they are of service to the profession and not to the public. But I venture to suggest that, in most, if not all cases, the specialist should be a consultant, pure and simple, and his advice sought only in conjunction with the ordinary medical attendant, or on the recommendation of an *all round* physician and surgeon." This truly ought to be the sphere of the specialist, and were such the case, no objection could be urged against specialism in medicine, since it would be productive of very much unalloyed good.

It is universally admitted that when a man labors day after day in the same line of thought, his perceptions become contracted, his opinions biased, and his jugdment, outside of this special groove, faulty. When a man devotes his life to the exclusive study and treatment of affections of the eye, he soon falls behind the progress of the day, in general medicine, and when called upon to treat a patient, no matter what the nature of the departure from health may be, he is very prone, oftentimes unconsciously to himself, to view the diseased condition through the agency of his favorite and most familiar instrument, the ophthalmoscope, and to give undue prominence to any ocular symptom that may be present, to the neglect or absolute disregard of the more important element which is truly the cause of the disease. With the general practitioner, the case is far different. Accustomed daily to examine a variety of diseased conditions, with their pathological changes seated in different parts of the body, and of a nature the one directly opposite to the other, his comprehension becomes broader day by day, and he is now prepared and ready to give due importance to symptoms that might be overlooked by the specialist, always eagerly looking for symptoms referable to the domain of his favorite study. Therefore, it would be well if a person in poor health would first consult some general practitioner. If, after a careful examination, this doctor discovers the original seat of the disease to be located in the eye, the ear, or the nervous system, he should recommend a consultation with some competent specialist in whichever branch the disease belongs. The examination should be made by this gentleman, and in a subsequent consultation between the specialist and the regular attendant, the plan of treatment should be mapped out, to be carried into effect by the latter. Examinations and consultations should take place as often as considered necessary. In the meantime the general practitioner is prepared and competent to treat any general complications that may arise in the course of the local disease. Or, suppose the disease is made out to be purely a local one, without any constitutional trouble whatever, then might the general practitioner hand the patient over absolutely to the specialist, for relief. The principal objection which the profession see in

specialists, and the greatest evils resulting from the present system, is due to the fact that, as a class (there are some noted exceptions), they resort to judicious but extensive personal advertising, by which means they secure many patients not afflicted with any of that class of diseases of which they have made a special study, but suffering from a general diseased condition, which properly comes under the domain of general medicine, and which they are incompetent to intelligently treat; thus bringing odium and disrepute upon the profession and its members at large. By resorting to the measure recommended by the *Lancet's* correspondent, specialism would be recognized as a valuable branch of medical science, and that class of practitioners would be regarded by the general physician as very valuable aids in the treatment of disease.

THE DANGER OF ADMINISTERING ANÆSTHETICS WITHOUT WITNESSES.

This subject has been written upon time and again, and physicians have been repeatedly warned not to give an anæsthetic to any one, but in an especial manner to avoid using them with females, unless in the presence of witnesses. Yet the advice is unheeded, and every now and then we hear of some unfortunate results from this negligence. This time it comes from the West. An old and prominent physician was visited by a beautiful young lady, for treatment for some sexual disorder. The lady belonged to the blue blood of the city, while the physician had been her grandparents' attendant, and had for years been the family physician. On one of her visits he informed her that an operation was necessary, and induced her to take some anæsthetic. Subsequently, not improving, she consulted another physician, who told her that she was pregnant. In due time a child was born.

The lady made no effort at concealment, but in a short time brought an action for damages against her old doctor. He publicly denied the charge, but refused to go into court and do so under oath. After a few minutes' deliberation only, the jury brought in a verdict against the doctor, assessing the damages at fifty thousand dollars. The verdict was received with such open manifestations of approval from the judge, as well as the audience, the former publicly shaking hands and congratulating the young lady in court, as to leave no doubt of the sympathy of the public. The case is a sad one; whether guilty or not, this old and established physician has been ruined, socially and professionally, forever.

It should be made a rule, never to be broken, by every physician, when he commences the practice of medicine, to refuse absolutely to administer an anæsthetic to any woman alone, no matter what the collateral circumstances may happen to be.

Women are peculiar and unreliable, and there is no accounting for the queer notions they may sometimes get into their heads; so that no physician is surely safe from trouble who has passed a period alone with a woman who has been made unconscious by an agent administered to her by him.

Notes and Comments.

The Working Zone of Anæsthetics.

From the London *Medical Record* we note the following valuable conclusions arrived at by M. Paul Bert, the French Minister of Public Instruction, communicated by him to the Paris Academy of Sciences. His experiments were conducted on dogs, mice, and sparrows, who were kept in chambers containing air along with various proportions of some anæsthetic. In a graduated series of such mixtures of increasing strength, one is found just sufficient to cause insensibility, and proceeding higher, a dose is reached which kills. The interval between these points he calls the working zone. In the cases of chloroform, ether, amylene, bromide of ethyl, and chloride of ethyl, he found the fatal dose to be precisely double the anæsthetic dose. When an animal is made to breathe, in the way indicated, a mixture about the middle of the working zone, it is very quickly anæsthetized, and remains perfectly quiet during the whole experiment (two hours in some cases), not requiring any attention or concern. A very great contrast to the ordinary method by the compress or sponge. M. Bert points out that with the compress, a patient alternately breathes (according

to the amount of chloroform in the compress, or its distance from mouth and nose) a mixture of air and chloroform either below the active dose, within the working zone, or at or beyond the limit of safety. In the case of chloroform, the working zone is very narrow, since while two drachms in twenty-five gallons does not suffice to render a dog insensible, five drachms kills it. While with ether there is an interval of ten drachms between the active and the fatal doses. An anæsthetic acts, not by the quantity respired, but according to its proportion in the inspired air. M. Bert recommends the use of a mask, communicating by a tube with a zinc reservoir holding from fifty to seventy-five gallons of the anæsthetic mixture. The pulse and respiration need no attention. M. Bert's experiments give no guidance to determine the lower limiting dose; this question is still open. The ratio between the limiting doses of protoxide of nitrogen is as one to three.

Acupuncture in Nervous and Spasmodic Affections.

The *Journal des Sciénces Médicales*, for December, contains an interesting article on the above subject, by Dr. Arens, from which we extract as follows:—

The Doctor frankly admits that it was accidentally he at first used acupuncture, but that within the last few months it has given him most excellent results, in a number of local spasmodic affections. His first experience was with a lady, who for four months past had suffered from severe gastralgia, attended by nausea and frequent vomitings; this had finally produced considerable exhaustion. Having been called to her during the night, and finding her in great suffering, all other means having failed, he proposed relief by a hypodermic injection of morphia. He had with him Pravaz' injector, but the morphine solution was missing. It was then he bethought himself of acupuncture, and decided on making two subcutaneous punctures over the epigastrium, using for that purpose capillary trocars, which he left *in situ* for five minutes.

The pain diminished soon after the first puncture, and ten minutes later had entirely disappeared. It has not since then been felt, and the cure is a radical one.

Subsequently, in a case of nervous asthma, the Doctor again had recourse to acupuncture, with satisfactory results. The paroxysms were invariably checked, by simply introducing the trocar of an injector two or three times, under the skin, within a small space, on a line with the internal extremity of the clavicula. On several occasions, not having steel needles at hand, he made use of ordinary pins, and obtained quite as good results. This treatment was successful in over fifty instances. The attacks passed off within ten minutes, and the patient enjoyed quiet rest.

Finally, the Doctor used acupuncture with success in the case of a boy, thirteen years old, troubled with an almost constant nervous cough, lasting from morning till night. Three pins applied, as in the case of the asthma patient, and left in place for half an hour, cured the cough, which has not since then again appeared.

Cases of hysterical cough have likewise been cured, and in some instances, the paroxysms in whooping cough have been greatly relieved. Hence, the Doctor concludes by recommending a more frequent use of acupuncture, and suggesting that it may often advantageously replace hypodermic injection.

Writers' Cramp or Scriveners' Palsy.

Trousseau and other eminent authors have considered this as an incurable affection. The following case, reported by Dr. H. Vigouroux, in *Paris Médical*, Dec. 10th, 1881, will, therefore, be read with interst.

Mr. X, a bookkeeper, noticed that his handwriting was becoming illegible, the pen holder dropped from his fingers, despite his efforts to hold it, and his hand trembled whenever he attempted to write. He consulted several physicians, and followed different treatments, without obtaining any benefit. Finally, he consulted Dr. Vigouroux, who, without any hopes of positive success, advised a trial of the actual cautery. On the 4th of April three rows of five points were applied on the posterior face of the forearm, between the elbow and wrist. On the third day the patient began experiencing relief; pain had disappeared, there was less irritation, and greater ease in holding the pen, but the writing still remained scrawled. Other cauterizations were made on the 11th and 19th of the same month, and a decided improvement was noticeable. The third application was extended over the dorsal face of the hand, to the tip of the little finger, which was the seat of quite a sharp pain, owing to the cramped position in which the hand had to be held while writing. After a fourth application, made on the 3d of May, the handwriting became as perfect as before the cramp set in. To insure complete recovery, three other cauterizations were made, on the 17th of May, 21st of June, and 12th of July; since which the patient has experienced no further trouble whatever.

Iodide of Potassium in Frontal Headache.

The London *Medical Times and Gazette* says:—

Dr. Haley states, in the *Australian Medical Journal* for August, that for some time past he has found minimum doses of iodide of potassium of great service in frontal headache. A heavy, dull headache, situated over the brow, and ac companied by languor, chilliness, and a feeling of general discomfort, with distaste for food, which sometimes approaches to nausea, can be completely removed by a two-grain dose dissolved in half a wineglass of water, and this quietly sipped, the whole quantity being taken in about ten minutes. In many cases the effect of these small doses has been simply wonderful. A person who, a quarter of an hour before, was feeling most miserable and refused all food, wishing only for quietness, would now take a good meal and resume his wonted cheerfulness. The rapidity with which the iodide acts in these cases constitutes its great advantage.

The morbid condition here described is so very common, that we would invite the experience of any gentleman who may see fit to give this remedy a trial.

Medico-Legal Importance of Injuries to the Nails.

The *Journal des Sciénces Méd.* for November, 1881, contains the following:—

In the researches made by Bean on the growth and development of the nails, he studied the semeiological importance of the furrows, or depressions which are observed in a number of diseases, especially in febrile affections, and he called attention to the medico-legal importance which those furrows would have, in a case where the accused might have some interest in concealing the existence of an anterior disease, the date, duration, and details of which could thus be established. The medico-legal value of those suggestions have lately, and for the first time, been put to practical test by Mr. Contagne.

A burglary was committed during the night of October 28th, and owing to various traces, it was evident that the thief had wounded one of his fingers. A month later three men were arrested on suspicion of having done the deed. On examination, Mr. Contagne found that one of these men bore marks on the medius finger of the right hand, of a lesion of the nail, consisting in a scar about midway of the nail, caused, no doubt, by a wound on its external half, which, while serious enough to have interested the connection of that organ with its matrix, had healed without entailing any necessity for a new nail, and after a time, had only left a scar, due to imperfect nutrition. During the examination, the accused evinced great uneasiness, and affirmed that the scar was the result of a wound from a stone, received six months prior. The fallacy of this explanation was, however, evident.

It is known that the average growth of the nails on the index, the medius, and the annular fingers, is four millimeters a month.

At a second examination, made on the 30th of December, the distance between the lower edge of the scar and the lunula was found to measure eight millimeters, consequently, a wound at the base of the nail two months earlier, the date of the burglary, could have caused the scar; in other words, assuming the growth of this man's nails to have been normal, the scar indicated an injury received since, but not prior, to two months.

Three other measurements were made, at monthly intervals, so as to prove beyond a doubt that the man's nails grew in a normal manner, and it became, thereby, possible to overthrow his entire system of defence.

Excessive Development of the Breasts Early in Pregnancy.

The London *Medical Times and Gazette* records a case of this kind offered to the Surgical Society of Paris, by M. Monod, in which the breasts had acquired an enormous size by the fourth month of pregnancy. In two former pregnancies, in the same patient, a similar trouble had occurred, and in the second instance large quantities of milk were discharged. In the present case, this unusual development had occurred as early as the second month, and the woman was becoming very thin. The former pregnancies had terminated favorably. The question then arose, as to whether suction or the induction of premature labor was indicated. In view of the fact that suction would have the effect of increasing the secretion of milk, the weight of opinion was in favor of inducing premature labor, if the patient's health should become impaired.

Filaria Medinensis.

At a recent meeting of the Pathological Society of London (*Medical Times and Gazette*), Dr. Finlay exhibited specimens of filaria medinensis for Dr. Mackellar, of Glasgow, who holds that the local irritation caused by these worms is not set up by the death of the parent worm, but by the presence in the tissues of the young, escaped from the broken pieces of the adult female.

Ptyalism in Insanity Treated by Neutral Sulphate of Atropine.

In the *Paris Méd.*, Dec. 3d, 1881, we find a report of Dr. Daujat's therapeutic experiments with neutral sulphate of atropine, administered in the following way:—

℞. Neut. sulph. atropine, 30 cm.=gr. ivss.
Distilled water, 300 gm.=f℥ ixss.

That is 1 milligram to each gram of solution.

The following are his conclusions:—

1. Neutral sulphate of atropine is certainly very efficient in the treatment of ptyalism among the insane.

2. When it does not entirely cure salivation, it greatly reduces it, and on reappearance it never reaches its original intensity.

3. The cure of sialorrhœa usually requires a treatment lasting about three weeks, and the administration of the neutral sulphate of atropine in daily doses of from $\frac{1}{60}$ to $\frac{1}{20}$ of a grain, progressively increased.

4. The length of time required for treatment depends more upon the time sialorrhœa has existed, than on its abundance.

5. Sulphate of atropine agrees fairly well with insane patients, and its best effects have been obtained in cases complicated with broncorrhœa and epilepsy.

The Treatment of Gunshot Wounds of the Abdomen in Relation to Modern Peritoneal Surgery.

Dr. J. Marion Sims delivered an address on this subject which has been published in the *British Medical Journal*, from which we note the following salient points:—

The principles essential to success which must guide us in all operative treatment of abdominal wounds are—

1. All hemorrhages must be promptly controlled by pressure, ligature, or hæmostatic forceps.

2. The peritoneal cavity must be thoroughly cleaned after operation and before the abdominal incision is closed.

3. The abdominal incision, usually in the middle line, must be properly closed. The divided edges of the peritoneum should be included in the sutures that close the abdominal wound, for if they are not, their raw edges may become adherent to the intestine in such a manner as to cause obstruction to the bowel, when a fatal result may follow. Commenting on the drainage tube, he advocates its use, but cautions us against the danger of ventral hernia from its employment, and recognizes the necessity of discovering some method of avoiding this serious accident.

Sucrate of Lime Liniment for Burns.

In the *Concours Médical* we see that in place of the ordinary lime water and oil liniment, M. Constantin Paul recommends one made from sucrate of lime, according to the following formula: Slacked lime and sugar, in equal quantities, are triturated together. Water enough is then gradually added, until the mixture becomes very liquid. It is allowed to stand for forty-eight hours, and then filtered. The solution is evaporated to the consistency of a thin syrup, and this is mixed in equal parts with a solution consisting of one part of glycerine and three parts of oil. This liniment has the advantage of containing a larger proportion of lime in a given quantity. It is applied to burns and covered over with raw cotton.

Testing for Lead in Articles of Food.

We read in the *Concours Méd. No.* 47, of a new process by Dr. G. Ponchet, for the detection of lead in articles of food. The suspected article is treated with its own weight of fuming nitric acid, to which 22 per cent. of acid sulphate of potash is added. When the effervescence is over, an excess of sulphuric acid is added, so as to destroy all of the organic matter, and the whole mass is heated until entirely discolored. Water is then added, and without filtration all of the acid liquid is submitted to the action of four Bunsen elements. All the lead which is present collects on the platinum blade of the negative electrode. From this it is redissolved by nitric acid, again precipitated, and weighed in the form of sulphate.

Adulterated Opium.

The *Sanitary Engineer* calls attention to the fact that the higher grades of opium, rich in morphia, are adulterated or mixed with foreign substances, so as to bring the percentage of morphia down to a uniform standard. For this purpose powdered liquorice root has been used. The propriety of this dilution is then discussed, and the very pertinent question asked, "if proper, why is the dilution not openly admitted or stated on the label?" Whether justifiable legally, or not, it is morally wrong, and ought not to be tolerated. There is one effectual way of stopping it. Every physician should examine the quality of the opium used by the druggist to whom he sends prescriptions, and if found to be adulterated, request him to procure the pure article, or, as an alternative, if the druggist fails to do so, send his business to some one who will.

The Microbi of Blennorrhagic Pus.

The *Journal des Sciénces Médicales*, for November, 1881, states that these microbi have already been noticed, but that Mr. Weiss contributes additional interesting data on the subject. The pus examined was taken from both men and women, and all necessary precautions observed. In every case, under the microscope, in the midst of the pus globules and epithelial elements small bodies could be seen, either alone, or united in pairs, or forming more numerous groups, and arranged after a special manner. These corpuscles always have a characteristic appearance. Mr. Weiss examined pus from thirty-two patients, and in each case he found similar parasitical forms. As a check, he examined pus from simple urethritis, balanopostitis, soft and syphilitic chancres, buboes and leucorrhœa, but in no case could he discover the spe cial elements which he considers characteristic of blennorrhagia. Experiments for the purpose of propagation would now be interesting; but they have not, as yet, been undertaken. As regards treatment, Mr. Weiss particularly recommends the parasiticidal qualities of hypermanganate of potassium. In Dr. Spillman's service, in all cases of vaginal blennorrhagia treated by injections with a solution of this salt, in the proportion of 0.25 centigram to the thousand, a rapid and extensive decrease in the number of microbi was noticed; they were found to have lost their coating and to have suffered changes indicating that they had been altered or destroyed by the application of this substance.

Vowels and Consonants.

The physiology of the voice has equal interest for laryngologists and linguists. One of the former, Dr. C. Seiler, of this city, has sent us a reprint from the *Archives of Laryngology*, in which he attacks the definition of vowels and consonants as generally accepted. He claims that the vowels and consonants are not pronounced separately, and that both are essentially vocal, differing from each other only by variations of timbre.

There are grave difficulties in accepting this view. The essential difference between vowels and consonants is not a device of grammarians, as Dr. Seiler says (page 2), but rests on a physiological distinction. The quality of the vowel depends on the length of the vocal tube through which the air is propelled; whereas, a consonant arises from narrowing or closing the tube in some part of its course. There are consonant sounds which have nothing vocalic in them; as, for example, the "explosives" of Central America, the "clucks," of the Selish, and the "inspirates," of the Hottentots.

The consonants are the fixed and voluntary parts of speech; while the vowel sounds are variable and involuntary, as we notice in the cries of pain or joy, the wailing of babes, and the sounds of lower animals and unconscious natural objects.

Fatal Peritonitis from a Vaginal Injection of Acetate of Lead.

The following case, reported in *Paris Médical, No.* 49, seems to be in favor of the now generally contested possibility that a fluid injected in the vagina may find its way into the abdominal cavity, through the Fallopian tubes.

A woman, 22 years old, was suffering from a severe attack of leucorrhœa. Injections of acetate of lead were prescribed, and these were continued for ten days, with good results. On the eleventh day the injection was taken rather hastily, owing to some interruption, and immediately after the woman complained of violent pains in the abdomen; she became deathly pale and fainted. Dr. Baum, the attending physician, was called in, and diagnosed acute peritonitis, from which the patient died, seventy-two hours after. The autopsy showed that, besides the ordinary lesions of peritonitis, a precipitate of sulphate of lead had been formed on the entire serous surface of the large intestine and across the whole hypogastrium, even as high as the umbilicus. This precipitate had the appearance of small, grayish-black, round peas, which, in some places. were very thickly distributed, while in others only a few could be seen.

Blennorrhagia Treated by Chlorate of Potash.

The *Paris Médical*, Dec. 3d, 1881, reports that Zeitlin has treated fourteen cases of blennorhagia with chlorate of potash, administered internally, in daily doses of three grams (grs. xl) according to Dachman's method. The results have always been satisfactory. After a few days micturition becomes painless, erections cease, and the discharge is less abundant, and more serous.

The happy effects of this salt are due to the rapidity with which it is excreted by the kidneys, without any change in its composition, and to its local action on the urethral mucous membrane.

Good results have also been obtained with chlorate of potash, prescribed as an injection, and in cases of blennorrhagic or other cystitis its internal use has been found beneficial.

On the Use of Iodoform Spray.

In the *Journal des Sciences Méd.* for December, 1881, M. Dujardin-Beaumetz recommends a new method for the use of iodoform in the case of syphilitic ulcerations, or those attending vaginitis. By means of the spray, he applies, on the affected parts, a solution of iodoform in ether, of which the following is the formula:—

℞. Iodoform, gr. xv
Ether sulph., ℥ iij. M.

The spray supplies a regular tenuous deposit of iodoform which reaches every fissure. In this way it is possible to reach those deep ulcerations of the throat which are otherwise so difficult to get at. The cure of vaginitis is explained by the effects of iodoform on the little ulcerations of the vulva, which are almost always a determining cause in all painful contractions of the ring. Hence, iodoform is of no service in any form of vaginitis, other than that due to ulcerations or fissures. The author has made no experiments with his process on anal fissures, for which he still believes that dilatation is indicated, but he advises its use in the treatment of vaginitis.

Uterine Colic Caused by the Entrance of a Leech into the Uterus.

In the *Rocky Mountain Medical Times*, Dr. S. Cole reports a curious case. He desired to apply leeches to the cervix uteri. After plugging with cotton the canal of the cervix, he put two leeches into the speculum. They failed to take hold, and after working with them for half an hour, he plugged the vagina with cotton, hoping thereby to hold them in position and thus induce them to bite. Very soon the woman was seized with severe uterine colic. Upon removing the cotton from the vagina he found only one leech. The plugging had fallen out of the cervix and leech number two had crawled into the womb. A uterine probe passed into the womb made the leech so uncomfortable that he soon appeared at the os and crawled slowly out. Had this procedure been unsuccessful, he would have resorted to an intra-uterine injection of warm salt water, salt being very repulsive to leeches.

Warm Ox Blood in Phthisis.

Dr. Bernard, in the *Journal de Thérapeutique*, recommends this rather disgusting remedy as of benefit in the early stages of tuberculosis. The *modus faciendi* is very simple: Every morning the patient goes to a slaughter house and drinks, on an empty stomach, a glassful of freshly-drawn warm ox blood. After a few days, if no vomiting takes place, the dose is increased to two glassfuls. This treatment must be followed to the exclusion of all others, for at least a year. The benefits which have invariably attended it, and which soon show themselves, are regularity of the bowels, relief from coughing, and a return of appetite.

A Dyspeptic Nurse.

Speaking of the character of the attendants of a sick person, Dr. J. Milner Fothergill says: "A pious widow, with dyspepsia and strong religious convictions, is a ghoul when illness is about. She sucks the life out of an invalid, like a moral vampire. As life ebbs she is sustained, and when the invalid has passed the portals of another world she goes away edified, strengthened and encouraged in her murderous mission, fully prepared to extinguish the lives of any number of relatives if ill luck should prostrate them upon the sick bed."

Locomotor Ataxy following Smallpox.

At a meeting of the Harveian Society of London (reported in the *British Medical Journal*), Dr. C. G. Henderson reported a case of confluent smallpox followed by ataxy. He also referred to similar cases recorded by Landouzy and others, and considered that the lesions causing the patient's symptoms were, probably, analogous to those found in diphtheritic palsy and other forms of paralysis noted after acute diseases. The prognosis is favorable in such cases, since, in the majority of instances, it terminates in recovery.

Correspondence.

Venesection in Pneumonia.

Ed. Med. and Surg. Reporter:—

I confess to having allowed my lancet to get rusty, in company with the great majority of my professional brethren. Recently, I visited Robert B., aged twenty, a strong, vigorous youth, ill with pneumonia, and for two days in succession I prescribed the usual remedies, internally and externally. On my *third* visit I found the affected lung, the right, in such a state of engorgement, and the symptoms of oppression of the circulation so alarming, that I tied up the young man's arm and drew fourteen ounces of blood. The pulse came down, the duskiness of the face disappeared, the breathing became easier, and in forty-eight hours my patient was surely (and rapidly) convalescent, making the duration of the active stage, with two days lost in the beginning, before bleeding was resorted to, less than six days. Comment is needless. I want to thank Dr. Corson, for his articles on this subject rang in my ears during those *two* days.

Preston, Maryland. H. F. Willis, M.D.

News and Miscellany.

New York State Medical Society—Seventy-sixth Annual Meeting.

The Society met in annual session, at Albany, in Agricultural Hall, on Tuesday, February 7th, The meeting was called to order at 10 o'clock. by the president, Dr. A. Jacobi, of New York City, and the exercises were opened with prayer by the Rt. Rev. Bishop Doane.

The President then delivered his inaugural address. He said—

Mr. Vice-President, Members and Delegates: "The third quarter of our first century is just closing. The history of these seventy-five years is of vast importance. At the time when this Society was founded, Bichat first thought of establishing, on a sound basis, a pathology of the tissues. Those times were still the periods of systems and schools; ours has succeeded in establishing scientific medicine on the sound foundation of close observation of the histological elements, and of experiment. In all of the eighteenth century, it was not the professors, but the practitioners who improved medical science. It is a glorious fact in the history of the profession at large, that almost no year has elapsed without the discussion of proper measures for the advancement of medical education. This fact is in accordance with all our republican habits and institutions which stimulate the masses into action in behalf of the general good. In the interest of both the public and the profession, medical education ought to be of the most advanced kind, and the license to practice ought not to be easily obtained.

Perhaps it cannot be proven that any medical schools ever opposed the establishment of a State Board of Examination, which alone might be authorized to convey the license to *practice*, the right of the college to convey diplomas notwithstanding. If it ever did, it is not probable that any college would now oppose any such movement, which I hope will be set on foot and result in the Legislature passing a proper law.

It is claimed by many that a coöperation with the homœopaths, for the purpose of arranging State examinations would not be out of place at the present time. It is generally asserted by many that there are good reasons for abolishing the boundaries between the several classes of medical men altogether. The homœopaths claim that they do not differ from us any longer, do not mean to differ from us, as formerly they did, and proudly claimed to do. If we have reason to believe that medical science is one and indivisible, and based on logic and experimentation, we may overlook differences and meet with a spirit of reconciliation those who do not encounter us any more, so they say themselves, with the dicta of a school or a sect, but who claim that each individual man among them stands on his own feet, and does his own thinking. A crowd of men facing the profession with the cry of "*similia similibus*," and "no quarter," exclude themselves, and cannot expect kind treatment at our hands. Besides, we are not the only class of what the State calls "lawfully qualified practitioners." It is necessary that in many steps to be taken before the legislature, we should be in full concord with those who share with us the honor of being called lawful practitioners. I will abide by whatever decision may be rendered the Committee on Revision of the Code of Ethics."

Referring to hygiene, the president said: "I have a word to say in regard to some contagious diseases. It is certain that both scarlatina and diphtheria are contagious, and it is also certain that this contagion extends over the whole period of the disease, and is enhanced by the accumulation of the poison produced by the accumulation of cases. It is also certain that diphtheria will infest all the surroundings of some patients, who will not get well unless removed from them. It is certain that isolation is of paramount importance in these diseases. I hope that a motion will prevail, to suggest the necessity of establishing hospitals for the treatment of diphtheria and scarlet fever within the limits of the large cities. Their proximity need be no source of danger. In conclusion, Dr. Jacobi directed the attention of the Society to the '*danger to life and limb of factory children.*' He recommended that children employed in factories should be under official supervision. They should be examined physically before being allowed to work. No night or Sunday work should be permitted. They should not be allowed to work before the age of puberty."

As an appropriate termination to his able address, the president said: "Twenty-eight years ago, a young refugee from a European State prison set foot on the hospitable shores of this continent. The homeless wanderer is to-day the proudest of your number, for a year ago this week you elected him to the most honorable and honored position the profession of this great State can fill, the first foreign-born president of this Society, so far as I know. I know there is no national profession with the same spirit of hospitality to both new men and new ideas; the same impartiality and absence of territorial narrow mindedness, which is prevalent among the medical citizens of the United States. May that spirit remain intact and chaste for the fourth quarter of this century, and for centuries to come, in the life of the Medical Society of the State of New York." After the reading of the president's address the usual committees were appointed, and general preliminary business transacted.

The first paper read was by Dr. F. R. Sturgis, on "Hints and Thoughts on Medical Education." The essential points of this address were that medical education in this country is inferior, because nearly all the medical schools are private business enterprises, and must be conducted to pay running expenses, if nothing more; therefore, bait must be set to lure money from the pockets of would-be physicians; and the suggestion that every professor be paid a salary sufficiently large to enable him to devote his time exclusively to teaching and keeping abreast of the times. (This course has been adopted by the University of Pennsylvania, under the management of Provost Pepper.—Ed.) Dr. Sturgis quoted from President Elliott, of Harvard, "That the University should be more concerned to have a very *good* school of medicine than a very *large* one."

After discussion, the second paper, on "De-

fective Construction of Thermometers," was read, by Dr. E. R. Squibb. Papers were also read by title, as follows: "Obituaries of Dr. Levant B. Cotes, by Dr. William Warren Potter, of Buffalo; and of Dr. John F. Whitbeck, by Dr. H. H. Langworthy, of Rochester."

The next paper was by Dr. W. S. Ely, of Rochester, entitled, "Note on Beef Juice."

At the afternoon session, Dr. S. O. Van der Poel read a paper on "The Present Condition of the Tuberculosis Question." Dr. W. W. Potter, on "Genu-Pectoral Posture in Retro-Displacements of the Uterus and Prolapsus of the Ovaries." Dr. E. M. Moore, of Rochester, gave a verbal "Report of a Case of Extraordinary Bone Development." Dr. E. E. Seguin, of New York, read a paper on "Effectual Dosage of Certain Remedies in the Treatment of Nervous Diseases." Dr. Charles S. Bull, of New York, on "Syphilitic Diseases of the Lachrymal Apparatus," and Dr. L. E. Felton gave a verbal description of a new galvanic battery, of his invention. The meeting then adjourned.

At the evening session, the committee appointed to revise the code of ethics made the following report:—

Code of Medical Ethics.

I. *The Relations of Physicians to the Public.*
II. *Rules Governing Consultations.*
III. *The Relations of Physicians to Each Other.*

I. THE RELATIONS OF PHYSICIANS TO THE PUBLIC.

It is derogatory to the dignity and interests of the profession for physicians to resort to public advertisements, private cards, or handbills, inviting the attention of individuals affected with particular diseases, publicly offering advice and medicine to the poor without charge, or promising radical cures; or to publish cases or operations in the daily prints, or to suffer such publications to be made; or through the medium of reporters or interviewers, or otherwise, to permit their opinions on medical and surgical questions to appear in the newspapers; to invite laymen to be present at operations; to boast of cures and remedies; to adduce certificates of skill and success, or to perform other similar acts.

It is equally derogatory to professional character, and opposed to the interest of the profession, for a physician to hold a patent for any surgical instrument or medicine, or to prescribe a secret nostrum, whether the invention, or discovery, or exclusive property, of himself or of others.

It is also reprehensible for physicians to give certificates attesting the efficacy of patent medical or surgical appliances, or of patented, copyrighted, or secret medicines, or of proprietary drugs, medicines, wines, mineral waters, health resorts, etc.

II. RULES GOVERNING CONSULTATIONS.

Members of the Medical Society of the State of New York, and the medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine. Emergencies may occur in which all restrictions should, in the judgment of the practitioner, yield to the demands of humanity.

The following rules should be observed in conducting consultations:—

The examination of the patient by the consulting physician should be made in the presence of the attending physician, and during such examination no discussion should take place, nor any remarks as to diagnosis or treatment be made. When the examination is completed, the physicians should retire to a room by themselves, and after a statement, by the attending physician, of the history of the case and of his views of its diagnosis and treatment, each of the consulting physicians, beginning with the youngest, should deliver his opinion. If they arrive at an agreement, it will be the duty of the attending physician to announce the result to the patient, or to some responsible member of the family, and to carry out the plan of treatment agreed upon.

If in the consultation there is found to be an essential difference of opinion, as to the diagnosis or treatment, the case should be presented to the patient, or some responsible member of the family, as plainly and intelligently as possible, to make such choice or pursue such course as may be thought best.

In case of acute, dangerous or obscure illness, the consulting physician should continue his visits at such intervals as may be deemed necessary by the patient or his friends, by him, or by the attending physician.

The utmost punctuality should be observed in the visits of physicians when they are to hold consultations; but as professional engagements may interfere or delay one of the parties, the physician who first arrives should wait for his associate a reasonable period, after which the consultation should be considered postponed to a new appointment. If it be the attending physician who is present, he will, of course, see the patient and prescribe; but if it be the consulting physician, he should retire, except in an emergency, or when he has been called from a considerable distance, in which latter case he may examine the patient, and give his opinion in writing, and under seal, to be delivered to his associate.

III. THE RELATIONS OF PHYSICIANS TO EACH OTHER.

All practitioners of medicine, their wives, and their children while under paternal care, are entitled to the gratuitous services of any one or more of the faculty residing near them, whose assistance may be desired.

Gratuitous attendance cannot, however, be expected from physicians called from a distance, nor need it be deemed obligatory when opposed by both the circumstances and the preferences of the patient.

The affairs of life, the pursuit of health and the various accidents and contingencies, to which a medical man is peculiarly exposed may require him temporarily to withdraw from his duties to his patients, and to request some of his professional brethren to officiate for him. Compliance with this request is an act of courtesy which should always be performed with the utmost consideration for the interests and character of the family physician, and when exercised for a short period, all the pecuniary obligations for such service should be awarded to him. But if a member of the profession neglect his business in quest of

pleasure and amusement, he cannot be considered as entitled to the advantages of the frequent and long-continued exercise o the fraternal courtesy without awarding to the physician who officiates the fees arising from the discharge of his professional duties.

In obstetrical and important surgical cases, which give rise to unusual fatigue, anxiety and responsibility, it is just that the fees accruing therefrom should be awarded to the physician whoofficiates.

Diversity of opinionand opposition of interest may, in the medical as in other professions, occasion controversy and even contention. Whenever such cases unfortunately occur, and cannot be immediately terminated, they should be referred to the arbitration of a sufficient number of physicians before appealing to a medical society or the law for settlement.

If medical controversies are brought before the public in newspapers or pamphlets, by contending medical writers, and give rise to or contain assertions or insinuations injurious to the personal character or professional qualifications of the parties, the effect is to lower, in the estimation of the public, not only the parties directly involved, but also the medical profession as a whole. Such publications should, therefore, be brought to the notice of the county societies having jurisdiction, and discipline inflicted, as the case may seem to require.

Wm. C. Wey, M.D., *Chairman.*
C. R. Agnew, M.D.,
S. Oakley Vander Poel, M.D.,
Wm. S. Ely, M.D.,
Henry G. Piffard, M.D., *Secretary.*

The discussion which followed the reading of the report was long and animated, and participated in by Drs. Roosa, Van der Poel, Piffard Sturgis, Agnew, and Noyes, of New York city; Hutchinson, of Utica; Ely, of Rochester; Mosher, of Albany; Wey, of Elmira; Squibb, of Brooklyn.

The president delivered his annual address in the Assembly Chamber of the New Capitol. He hose for the subject, "Infant Feeding and Infant Foods." From forty to fifty-three per cent. of the infants that die perish from diseases of the digestive organs. During the first two months of an infant's life, the mother who will refuse breast milk, except from sickness, is an accomplice in the death of her child, should such an event follow.

The common fault of breast milk is an undue percentage of fat, cheese, salt, etc., due to the condition of the blood. Where cow's milk is used the animal should be so fed as to reduce the proportion of fat.

The speaker then described the institutions at Stuttgart and Frankfort-on-the-Main, where cow's milk is prepared for infant food. Among the board of directors are a veterinary surgeon and a chemist. No cows are used except between the ages of three and eight years. The stables are well ventilated, the floors of the stalls cemented and connected by drains with the city sewers. Dry food is used, consisting of certain and stated proportions of such fodder as have proved the best. The stables are situated near the city, so that the milk will not suffer by transportation, and it is delivered in tightly corked bottles. The milk of a special cow is not given to a special baby, but all is mixed together. The speaker then denounced many of the so-called "infants' food," and pointed out wherein they were deficient.

At the conclusion of the address, a vote of thanks, moved by Dr. S. O. Van der Poel, was unanimously carried.

The annual banquet then took place at the Delavan House. The following toasts were proposed and responded to —

"The Clergy," Rev. Wesley R. Davis; "The Law," Mr. J. Irving Browne; "The Press," Mr. St. Clair McKelway; "The Medical Society of the State of New York," Dr. William Govan; "The ex-Presidents," Dr. S. O. Van der Poel; "The Business Committee," Dr. D. B. St. John Roosa; "The State Board of Health," Dr. Elisha Harris; "The Undertaker," Gen. Chas. Hughes; "The evening of February 8th, 1882," Dr. Frazier; "The Medical Expert," Dr. John P. Gray.

Second Day's Proceedings.

WEDNESDAY, FEBRUARY 8TH.

Society called to order at 10 A.M. Prayer by Rev. Dr. Davis. Dr. Porter reported, as Trustee of the Merritt H. Cash Prize Fund, that there was available for a prize $127. Dr. E. V. Stoddard made a verbal report for the Committee on Hygiene. Dr. Squibb moved the appropriation of $100 for the necessary expenses of the Committee on Experimental Medicine. Motion carried. Dr. Daniel Lewis, of New York, read a paper on "The Treatment of Scarlatina," speaking highly of digitalis. Dr. Lorenzo Hale, of Albany, gave "An Improved Dressing for Fractured Clavicle." Dr. H. Knapp, of New York, read a paper on "Croup of Conjunctiva," with remarks on contagious forms of conjunctival inflammation. Dr. John O. Roe, of Rochester, read a paper on "Internal Œsophagotomy."

AFTERNOON SESSION.

Dr. L. Elsberg read a paper on "The Laryngeal Muscles of the Voice, and the Laryngoscopic Images of their Paralysis." Dr. Wm. Hales on "Improved Methods in Laboratory Construction." A biographical sketch of Dr. S. Beebe was read by title. Dr. Austin Flint read a paper on "Hepatic Flatness on Percussion, as Proof against Intestinal or Gastric Perforation in Cases of Acute Peritonitis." A paper on "Treatment of Double Talipes Varo-Equinis by Open Incision," was presented by Dr. A. M. Phelps, of Chatauquay.

Dr. George H. Fox, of New York, read a paper on "The Treatment of Wine Mark by Electrolysis." The object arrived at is to excite sufficient inflammation to destroy the fine network of capillaries. He uses a small brass disk, which carries numerous fine cambric needles, and is attached to the negative cord of a constant battery; they are quickly pressed into the skin and allowed to remain from ten to thirty seconds. The effect of the electrolysis becomes evident in about three weeks. There are some dangers to be apprehended, but generally the operation produces marked improvement.

A case of "Subcutaneous Section of the Femur" was reported by Dr. A. Van Derveer. The operation performed for the relief of anchylosis was quite successful. Dr. H. D. Noyes read a paper on "Division of Optic and Ciliary Nerves for Sympathetic Ophthalmia."

A memoir of Dr. James P. White, of Buffalo, was presented by Dr. Austin Flint, of New York, and Dr. L. Duncan Bulkley read a paper on "The Malignity of Syphilis," with an analysis of 450 cases. After which the Society adjourned until Thursday, February 9th, at 10 A.M.

Third Day.

The Society convened at 10 A.M., and the services were opened with prayer by the Rev. Mr. Ecob.

The following papers were read, by title or otherwise:—

"Application, by Insufflation, of Medicated Powders to the Upper Air Passages, for the Relief of Catarrhal Conditions." "Inflammation of the Shoulder Joint, resulting from Hemiplegia." "Report of a Case of Molluscum Fibrosum." "The Early Diagnosis of Pott's Disease." "The Significance of Pain Referred to the Ear." "On the use of Avena Sativa." "Cases of Glaucoma, in which iridectomy of one eye seemed to precipitate an attack of Acute Glaucoma in the other eye." "A few Original Thoughts on Cholera." "Facial Paralysis Occurring in Connection with Aural Diseases."

The recommendation of the committee relative to the appointment of a State Board of Examiners by the Regents of the University was adopted.

The following officers were then chosen for the ensuing year:—

President—Dr. Harvey Jewett, of Ontario.

Vice-President—Dr. E. D. Ferguson, of Rensselear.

Treasurer—Dr. Charles H. Porter, of Albany.

Censors—S. D., J. W. S. Gouley, C. R. Agnew, Austin Flint, of New York; E. D., C. E. Nichols, M. H. Burton, W. S. Cooper, of Troy; M. D., Alonzo Churchill, S. G. Wolcott, J. K. Chamberlayne, of Utica; W. D., C. C. Wyckoff, Thos. F. Rochester, of Buffalo, and Henry Lapp, of Clarence.

Committee of Arrangements—Drs. S. B. Ward, W. S. Ely and J. S. Mosher, of Albany.

Committee on By-Laws—Drs. W. C. Way, of Elmira; Alex. Hutchins, of Brooklyn, and Wm. Manlius Smith, of Manlius.

Committee on Hygiene—Drs. E. V. Stoddard, Rochester; Stephen Smith, New York; Jacob S. Mosher, Albany; J. Foster Jenkins, Yonkers; Caleb Green, Homer; Edward Hutchinson, Utica, and Theodore Dimon, Albany.

Committe on Legislation—Drs. Wm. H. Bailey and C. Van Derveer, Albany, and F. R. Sturgis, of New York.

Committee on Medical Ethics—Drs. R. C. Agnew, New York; E. M. Moore, Rochester, and S. O. Van der Poel, of New York.

Committee on Prize Essays—Drs. Thomas F. Rochester, Buffalo; W. S. Ely, Rochester, and W. W. Potter, of Buffalo.

Committee on Publication—Drs. Wm. Manlius Smith, Manlius; Charles H. Porter, Albany; H. D. Didama, Syracuse, and J. Foster Jenkins, of Yonkers.

Censor of College of Medicine, Syracuse University, John W. Whitbeck.

Drs. Charles N. Hewett, Red Wing, Minn.; Roberts Bartholow, Philadelphia, and Sidney Ringer, London, were elected honorary members.

Drs. Theodore G. Wormley and William Goodell, of Philadelphia, were declared eligible to honorary membership.

The following gentlemen were appointed delegates to the State Medical Societies:—

New Jersey: N. C. Husted, Westchester; Wm. Govan, Stony Point, and Jas. C. Hutchinson, of Troy. Massachusetts: G. G. Monson, St. Lawrence; E. N. Brush, Onedia, and Peter V. S. Pruyn, of Columbia. Ohio: Thos. R. Pooley, of New York. Pennsylvania: H. C. May, Steuben; S. Van Etten, Orange, and J. W. Moore, of Albany. Vermont: Lyman Barton, Essex, and A. M. Phelps, of Franklin. New Hampshire: Wm. M. Chamberlain.

Delegates to Canadian Medical Association—Drs. John Guerin, Cayuga; D. V. O'Leary, Albany; L. E. Felton, St. Lawrence, and C. C. Dodge, of Clinton.

The following delegates were named to the American Medical Association:—

Drs. W. C. Wey, Elmira; C. R. Agnew, H. G. Piffard, S. O. Van der Poel, D. B. St. John Roosa, F. R. Sturgis, Daniel Lewis, A. Jacobi, F. H. Hamilton, Fordyce Barker, L. A. Sayre, Wm. M. Chamberlain, L. D. Bulkley, A. V. B. Lockrow, New York; W. S. Ely, B. M. Moore, Rochester; W. H. Bailey, Albany; E. S. Howe, Clinton; Harvey Jewett, Canandaigua; John P. Gray, Utica; T. B. Reynolds, Saratoga; N. C. Husted, Tarrytown; Geo. J. Fisher, Sing Sing; J. Foster Jenkins, Yonkers; Thos. F. Rochester, Buffalo; Fred. Hyde, Cortland; G. H. B. Spencer, Watertown; J. C. Hutchinson, E. R. Squibb, Brooklyn; Morris Perkins, Schenectady; Theodore Dimon, Auburn; and J. H. Chittenden, Binghamton.

President Jacobi then returned his thanks for the consideration with which he had been treated during his official career, and after a vote of thanks to the various committees, the Society adjourned *sine die*.

In conclusion, we would acknowledge our obligations to *The Medical Annals*, which was published daily, for much of the above report.

Baron Larry.

On the evening of February 6th, Professor D. Hayes Agnew delivered an address on the life and labors of this distinguished surgeon, before the Philadelphia Academy of Surgery. Jean Dominique Larry was born at Beaudeau, near the upper Pyrenees, July 12th, 1766. He was the author of the flying ambulance system during the Napoleonic wars, and the inventor of the lancet-pointed needle. In conclusion, Dr. Agnew said "Larry, as an operator, was judicious, but bold and rapid, and full of gentleness and sympathy. He was to surgery what Napoleon was to the army, the first and greatest." The lecture showed great historical research, and was a most interesting sketch of the life of one of the greatest of surgeons.

An Old Hospital.

The *Sanitary Engineer*, gives the following description of an old hospital on the Island of Malta, which illustrates very accurately the limited knowledge of architectural hygiene which obtained three hundred years ago. The site is the lowest on that side of the town, and all the ground falls towards it. The drains of the town were discharged into the sea, close to the building. Facing the sea, the hospital was exposed to the Sirocco, while it was protected from the healthy north and northwestern winds by the Fort of St. Elmo. The windows in the wards were very small and high, and all along their seaward side were ranged niches, which were used as latrines. Nearly 140 years later several new buildings were so erected as to shut out still more air and light from the original hospital.

Another Death from Supposed Hydrophobia.

Some time since a young lad was accidentally bitten in the finger by a pet dog. The wound was cauterized, and no more thought of it by his family. A month subsequently the boy complained of pain in the hand and forearm of the side that had been bitten. He was taken to a regular physician, and subsequently to an herb doctor. Finally, he was seized with convulsions and died. He was of an exceedingly nervous temperament, and had brooded over the injury. The question arises here, as in other similar cases, did not the boy die of imagination?

—The Edinburgh *Medical Journal* has a poem entitled—

A PSALM OF HEALTH,

From which we quote the following:—

"Tell me not, in scornful numbers
Sanitation is a dream;
Woe be to the man who slumbers,
Thinking drains are what they seem.

Drains are real, bad gas injurious;
If the grave is not our goal,
All past systems are but spurious;
Carefully re-drain the whole.

Ill-drained houses all remind us
Sanitation is sublime;
Shunning the association,
Henceforth, shall be held a crime."

The Sizes of Distinguished Heads.

In *Nature*, Mr. Tuckett gives the following as the sizes of hats worn by different distinguished men. Lord Chelmsford, 6½ full; Dean Stanley, 6¾; Lord Beaconsfield, 7; the Prince of Wales, 7 full; Charles Dickens, 7⅛; Lord Selborne, 7⅛; John Bright, 7⅛; Earl Russell, 7¼; Lord Macaulay, 7⅜; Mr. Gladstone, 7⅜; Mr. Thackeray, 7⅝; Louis Philippe, 7¾; M. Julien, 7¾; Archbishop of York, 8 full.

Curious Malformation.

A curious case of malformation has occurred in the practice of Dr. Simon Kovrig, of Szamosujvar, in Hungary. The child, which was stillborn, has a "Janus head." At a point corresponding to the centre of the normal forehead, commence two completely developed faces with four eyes, two mouths, and two noses. Posteriorly, there is an ear on each side, and at the point of fusion of the faces anteriorly a third undeveloped ear is to be seen.

Investigations into Diphtheria.

Drs. H. C. Wood and Formad desire to know of the existence of an epidemic of malignant diphtheria, in order that they may continue their research upon the nature of the diphtheritic poison. Dr. Formad will go to any locality within eight hundred miles of Philadelphia. Letters may be directed to the University of Pennsylvania.

Vivisection.

—"Scientific experiments on organic life a necessity; no sin!" was the title of a sermon in favor of legitimate vivisection, delivered on Sunday evening, January 8th, by the Rev. Richard Hill, M.A., at St. Barnabas Church, Stockwell, England. Seats were set apart for the medical profession.

American Diplomas in Australia.

The Department of State has received an official communication from Adelaide, South Australia, from which it appears that an amendment has recently been effected in the medical laws of that colony, whereby the holders of foreign diplomas are entitled to be registered as duly qualified medical practitioners. The Department of State has accordingly been asked to furnish a list of all the schools of medicine in this country which issue diplomas or certificates of sufficient value to entitle their possessors to practice medicine in all its branches, and to hold government medical appointments. The necessary steps have been taken by our government to furnish this information, which will remove all obstacles in the way of American graduates practicing medicine in South Australia.

A Useful Book.

We have received very many letters like the following, which comes to us from a prominent New York physician:—

"Allow me to say a word of praise and recommendation of Napheys' *Modern Therapeutics*. I consider these volumes almost indispensable to every practicing physician, and of especial value to the younger members of the profession, who are not unfrequently at a loss to know how to combine medicinal agents in such a manner as to render them at once palatable and efficient. It is nothing less than a piece of professional good fortune for a practitioner to secure a copy of these works."

We make this quotation, not so much to bring these books to the notice of readers, as to illustrate their particular usefulness, which has not always been understood by those who have given them merely a passing examination.

Items.

—The American edition of Braithwaite is the *Quarterly Epitome*, not *Retrospect*, as we had it in a recent number.

—A man out West feared he was going to have the smallpox, and believing whisky to be a preventive, he drank about three quarts of it. A coroner's jury, the next day, rendered a verdict "that he died from excessive prophylaxis."

—A society of archæologists recently held a meeting. At the dinner a large fruit pie was produced. "What is it made of?" asked a visitor. "Blackberries, sir," said the first waiter. "Blueberries," said the second. "Whinberries," said the pretty maid. "Bilberries," said Professor Babington. "Whortleberries," said another botanist. "Huckleberries," said another. The first waiter, in despair, came to the most learned looking of the guests and said: "Sir, they say you are a good herbalist; what is the correct name of these berries?" "VACCINIUM MYRTILLUS," was the answer. Thereafter the waiter persisted in calling bilberry tart "*vaccination murderers.*"

OBITUARY NOTICES.

—Dr. M. C. Dean, formerly President of the American Dental Association, was found dead in bed at his home in Chicago, January 28th.

—Mrs. Mildred Smith Crosby, widow of the late Professor Alpheus Benning Crosby, M.D., of Bellevue College, New York, died at Galveston, Texas, recently. Mrs. Crosby was a daughter of the late celebrated Dr. William K. Smith, of Galveston.

—Among recent deaths was that of Dr. Joseph Barrett, of Middletown, Connecticut, in his 82d year. He enjoyed at one time a large practice, but gave it up to pursue geological studies. He discovered bird tracks in the Connecticut red sandstone, and became so enamored of such studies that he neglected his business and was popularly supposed to have become a monomaniac.

—Dr. Theodore Schwann, the well-known Belgian physiologist, died in January. Dr. Schwann was born in Neuss, in 1810, and received the degree of M.D. in Berlin, when twenty-four years of age. After serving as assistant naturalist in the Berlin Museum of Anatomy, he was appointed, in 1839, Professor of Physiology in the University of Louvain. Nine years afterward he left Louvain, to fill a similar position in the University of the Liege. Dr. Schwann was a member of the Brussels Academy, and in 1879 was elected a corresponding member of the French Institute. He was the author of numerous scientific works of great value.

QUERIES AND REPLIES.

J. K. L., of Pa.—We have received several letters from homœopathic physicians charging us with injustice in our editorial on "Consultations," especially complaining of our statement that such a consultation is, in a manner, "compounding a social felony." We take it for granted that any intelligent regular physician looks upon homœopathy as a delusion and an injury to science and to the public. If he does hold this opinion (whether right or wrong), for him to countenance this injurious delusion is nothing less, morally, than would be countenance and protection extended to any scheme for injuring people in person and property. This is what we meant, and we are convinced that we are right.

Dr. E. S., of Florida, asks us to correct and publish formula for "Delirium Tremens," April 30th, 1881, page 489. We have examined the formula there given, and the only exception we can note in it is the large dose of tinct. digitalis, two drachms. Such doses and even larger (f℥ss) have been used in delirium tremens with good results, though we would consider it rather reckless medication to employ such very large doses.

Dr. J. E. G., of Wisconsin, asks for a bread for diabetic patients.

Gluten flour, made, to our knowledge, by Farrell & Rhines, of Watertown, New York (and probably by others), is free from bran or starch, and possesses tonic and waste repairing properties. Its use would be indicated in diabetes.

Drs. B. and M., of Ohio.—Vitalized air is a catchpenny expression, and you do well to show up such attempts on public credulity.

Dr. D. A., of Ohio.—Please give exact reference to article on "Spectacles" you mention.

Dr. E. C. K., of Wis.—The fluoric acid referred to is a dilute, medicinal form of the chemical article.

BIRTHS.

VALENTINE.—At Guatemala, in January, Edith Rosette, daughter of Dr. F. C. and Mrs. Valentine.

MARRIAGES.

HABIRSHAW—READ.—On Wednesday, Feb. 1st, 1882, at Trinity Chapel, by the Rev. Dr. Eigenbrodt, John Habirshaw, M.D., and Adelaide M. Read, daughter of the late Arba Read, of Troy, New York.

KENNEDY—STARKS.—At Troy, New York, Feb. 1st, 1882, by Rev. George C. Baldwin, D.D., Dr. Robert Kennedy, Jr., of Philadelphia, Pa., and Miss Clarissa A., only daughter of the Rev. Dr. W. H. L. Starks, of Waterford, New York.

LITTLE—HETHERINGTON.—On Thursday evening, Feb. 9th, 1882, at the residence of the bride, by Rev. C. F. Turner, George Little, M.D., and Jennie Hetherington, both of Philadephia.

NEWPHER—KEPNER—On Wednesday, February 1st, 1882, at the residence of the bride's parents, by the Rev. J. A. Peters, John J. Newpher, M.D., of Mount Joy, Pa., and Ella E. Kepner, of Lancaster, Pa.

RANDLE—HARMER.—On January 3d, 1882, at the residence of the bride's parents, by the Rev. G. D. Carrow, W. H. Randle, M.D., of Jenkintown, Pa., and Miss Mellie L., daughter of Hon. A. C. Harmer, Germantown.

DEATHS.

BROWN,—On Thursday, January 26th, Dr. W. T Brown, of Cincinnati, Ohio, in the 47th year of his age.

DODGE.—In Sprinfield, Vermont, January 25th, William L. Dodge, M.D., aged 38 years, 7 months, 14 days.

PARRISH.—On the 29th ult., at his residence in New York, Miers Fisher Parrish, in the 30th year of his age, son of the late Dr. Isaac Parrish,

SHACKLETON.—In Auburn, California, January 22d, 1882, Dr. E. L Shackleton, formerly of St. Marys, Ohio, aged 42 years and 9 months.

SHARP.—In Salem, New Jersey, January 20th, Dr. Jacob T. Sharp, in the eightieth year of his age.

STARR.—Died, of hemorrhage of the lungs, at his residence, in Ames, Iowa, January 18th, Dr. Samuel J. Starr, in the 46th year of his age.

Smithsonian Institute

Compound Chlorate of Potash Lozenges

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

GONORRHŒA IN THE MALE; ITS NATURE, CAUSES, AND TREATMENT.

Delivered in the Medico-Chirurgical College of Philadelphia,

BY CHARLES L. MITCHELL, PH.D., M.D.,

Professor of Chemistry, Sanitary Science and Venereal Diseases.

(*Concluded from page* 172.)

We now come to the treatment of gonorrhœa. This is accomplished by two methods, the local, or external, and the internal. The former consisting of the use of injections, insufflated powders and medicated suppositories; the latter, the internal administration of certain remedies, generally balsamics. I am not an advocate of the latter method, for while in certain cases the remedies act advantageously, it is a slow, cumbrous, disagreeable style of treatment, often doing more harm to the system than good, by the disturbances in digestion it occasions. I rely much more upon injections and other local remedies. It will be well to discuss for a few minutes the urethral syringe, and its proper use. I first show you the ordinary glass penis syringe. It is the most extensively used of all the syringes, but is generally faulty in construction, the tip being too sharp, and apt to irritate the mucous membrane of the urethra. The packing of the piston is made of soft cotton twine, and is generally loose, causing the injection to spirt from the back part of the syringe. Should the packing be well done the instrument then works stiffly. Here are a number of other styles, some good, some bad, and some indifferent. The most of them have too sharp a tip. The best form of glass syringe is the P. P. bulb syringe. It consists of a hollow rubber ball holding about half a fluid-ounce, in which is fixed a glass tube about three inches long, terminating in an appropriate tip. By compressing the ball so as to force out the air, and then placing the end of the tube in the injection, a quantity of the latter will be drawn up, and can then be ejected by gently pressing the bulb. It is much more easily worked than the piston syringe, as the stiff movement of the latter will cause a nervous patient much trouble. As ordinarily found in the stores, the tip is also too sharp; but I here show you one which has been made to order, having the proper shaped end. This should be a cone, at the apex being the size of a bougie No. 13 French scale, at the base No. 30 French scale. When made of this shape it will fill up the meatus, without projecting far enough in to irritate the urethra. The hard rubber piston syringes are of much better workmanship than the glass, and consequently to be preferred. They are expensive however.

Another great trouble in syringes is that they are generally too small. A good penis syringe should have a capacity of from f℥ij to f℥ss, preferably the latter, as a smaller amount of fluid will fail to thoroughly distend the urethra and allow the injection to penetrate into every fold. You should direct the patient to first pass his urine, so as to thoroughly wash out the urethra and prevent any of the discharge from being carried back by the injection to a healthy surface, where it may cause an extension of the disease. Then direct him to assume the recumbent position, if possible, take the glans penis between the thumb and forefinger of the left hand, and separate the lips of the meatus, and

introduce the tip of the syringe, pressing it gently inward until it entirely fills the meatus. Hold it in position by gentle pressure of the lips of the meatus against the tip of the syringe, and then slowly force in the injection from the syringe, until the urethra is fully distended. Then remove the syringe, quickly slipping over the meatus the end of the forefinger, so as to keep the injection from escaping. The liquid should remain *in situ* for full five minutes, at the same time frequently stroking the under side of the penis, so as to thoroughly distribute the injection. At the end of that time let that injection escape.

The medicinal treatment of gonorrhœa may be divided into that of three stages: 1st. The incipient. 2d. The acute. 3d. The subacute or stage of decline. If you can see your patient when the attack is just beginning, you may, in some cases, succeed in aborting it entirely. This is done by injecting a solution of nitrate of silver into the urethra, of such strength as to induce an active inflammation, lasting for four or five days, and thus supplant the morbid action, which may last for a much longer time. This mode of procedure has been very justly condemned. In some few cases it may abort the disease; but in the greater majority it aggravates the inflammation and increases the suffering of the patient. The trouble is that a patient is seldom seen in the incipient stage, as the symptoms are then so slight as to be often overlooked. When he does come for relief it is from the suffering of the acute stage, and then this treatment will only heighten his torment. I believe, however, with a careful selection of cases you may sometimes succeed, provided the injection be not too strong. The strength formerly used was from 20 to 30 grains of nitrate silver to f℥j of water (used once as an injection), this is entirely too strong, and I must unhesitatingly condemn it, as it will nearly invariably produce stricture. I have operated on several cases of stricture produced in this manner. The formula recommended by Bumstead (argenti nitratis, grs. ss–iss. aquæ, f℥ vj) is much more safe; it is to be used at intervals of three or four hours. In the course of twenty-four hours the discharge decreases, grows thin and watery, and tinged with blood. Now is the time to stop injection, and omit all medication for a few days, until we see how much good has been accomplished. If the treatment is successful, the discharge will totally disappear in four or five days.

In the acute stage of gonorrhœa the proper regulation of the diet and habits of the patient is a matter of great importance. If you can keep him in bed for a few days you will accomplish a great deal. If the testicles are at all tender they should be placed in a suspensory bandage. The diet during the active stage should be non-stimulating but nourishing, and all indulgence in liquors, particularly beer, ale, etc., should be strictly forbidden. The bowels must be kept open.

The first point in the medicinal treatment should be relief of the painful micturition, and the swelling and congestion of the penis. As the urine in this affection is apt to be acid and irritating, we should endeavor to render it bland and alkaline in character, and we therefore administer such salts as are decomposed in the blood with the liberation of an alkali. These are the alkaline citrates, carbonates and bicarbonates, acetates, tartrates, etc. They should be administered in their appropriate doses, largely diluted with water. As regards the use of flaxseed tea, and all other demulcent diluents, they are old women's remedies, and simply useless. The best time to administer the alkalies is *two hours after meals*. The officinal liquor potassæ, in doses of from 10 to 20 drops, is also a very good remedy, administered in the same manner. A prescription which I often use, especially when there is increased frequency of micturition and chordee, is the following:—

℞. Potassii nitratis, ℥ ij
Potassii bromidi, ℥ ss
Morphiæ sulphatis, grs. ij
Ext. gelsemii, fld., f℥j
Syrupi, f℥j
Aquæ camphoræ, ad f℥ vj. M.

Sig.—A tablespoonful in half a tumbler of water, two hours after meals.

The urine should be repeatedly tested with litmus paper, and the quantity of alkali so regulated as to give it a neutral or slightly alkaline reaction. The penis should be kept lightly wrapped in a cloth constantly saturated with the following mixture:—

℞. Liq. plumbi s'ac, f℥ iij
Tinct. opii, f℥j.
Ft. misturæ.

In addition, the patient should be directed every morning and evening to immerse his penis for about fifteen minutes in hot water. This should be so hot as to be on the verge of scalding; thus applied the pain is greatly relieved and the swelling of the glans and prepuce soon disappears. Should the prepuce be greatly swollen and infiltrated, it may be necessary to slightly scarify or puncture it with a sharp-pointed bistoury, so as to deplete the part. Should the urethra be very

sensitive, the inflammation high, and the meatus much contracted, the above should constitute the entire treatment, and no local measures be instituted until the more active symptoms have subsided. In the majority of cases, however, the channel is not so sensitive as to prevent the use of a syringe, and an opiate injection can be administered in addition to the previous treatment. This should consist of the following:—

℞. Ext. opii aquosæ, ℈j
or
Morphiæ sulphatis, grs. iv
Ext. belladonna alc., grs. v
Mucilaginis cydonii,
Aquæ, āā f℥j. M.

Sig.—Add a teaspoonful to a tablespoonful of hot water, and use as an injection, every four hours.

As soon as the acute stage begins to subside, the local use of an astringent must be commenced. With this should be mixed an opiate, until all painful symptoms have disappeared. Probably the best and most commonly used astringent is the sulphate of zinc; following it are the subacetate of lead and the acetate of zinc, while the astringent salts of copper, iron and cadmium, and the vegetable astringents, tannic acid, kino, catechu, krameria, etc., etc., prolong the list. I rather prefer the sulpho-carbolate or salicylate of zinc. In commencing with an astringent injection, it should not be too strong, and should not contain more than ¼ gr. or ½ gr. of the weaker mineral astringents to the fluid-ounce; of the vegetable astringents more can be used, but the stronger mineral astringents, such as the chloride of zinc and sulphate of copper, must be given in very small doses, and had best be left for more chronic cases. A very soothing remedy in the subacute stage is the liq. plumbi s'ac:—

℞. Liq. plumbi s'ac, ℥ss–℥j
Morphiæ sulphatis, grs. iv
Glycerinæ, f℥ss
Aquæ, ad f℥iv. M.

Sig.—Use as an injection, four times daily.

The subacute stage is the only one in which the balsamics, such as copaiba and cubebs, etc., should be used. I do not depend much upon them. They are most useful in bladder complications, where they are extremely valuable. They should be given in small doses, in either the form of an emulsion, or in a soluble gelatin capsule; of these the soft capsules are much the best, as they are more easily swallowed and have no taste. The essential oil of sandal has been highly recommended, but I have no faith in it, as I have found it to have very little value, and to so saturate the patient with its peculiar odor as to make him an object of attention and remark.

In the latter stages of gonorrhœa, where the discharge is profuse and watery, and where there appears to be a loss of tone and a relaxed condition of the mucous membrane, you will find the oxide of zinc to be a valuable agent, either alone or combined with a small quantity of hydrastis canadensis.

℞. Pulv. zinci oxidi, ℥ij
Mucilaginis cydonii, f℥iij
Aquæ, ad f℥iv.
or
℞. Pulv. zinci oxidi, ℥ij
Ext. hydrastis, fld., f℥ij
Mucilaginis cydonii, f℥iij
Aquæ, ad f℥iv. M.

Sig.—Use as an injection, three times a day.

You will notice in a number of these formulæ I have used the "mucilago cydonii," or quince mucilage. This is a bland, cooling vehicle, which is very grateful as an injection.

Another method of treating gonorrhœa locally is by means of "insufflation," or blowing powdered medicaments into the urethra. It is a poor plan. Another and much better method, is by the use of urethral suppositories. They are made of different lengths, of cacao butter or gelatin, the latter being preferred, on account of its flexibility, and act even better than injections. They must not be used in the acute stages, as a general rule, but act very well in subacute and chronic conditions.

By the use of the different methods which I have at length detailed to you, with such modifications as your judgment will suggest, I think you will have very little trouble in curing the great majority of your cases of gonorrhœa. It is still remains for me to speak briefly of the treatment of the two complications of chordee and hemorrhage. Chordee is best treated by immersing the penis in hot water, and by the internal use of the bromides, opium, hops and lupuline, etc. If the case is at all severe, you will find the above remedies to be inadequate, and then you must rely upon opiate rectal suppositories. These should be of morphia, ext. opium, ext. belladonna, or some other anodyne, given in full doses until relief is obtained. A very good formula is the following:—

℞. Chloralis hydrat., ℥ss
Camphoræ, grs. xij
Morphiæ acetatis, grs. ij
Ol. theobromæ, q. s. M.
Ft. suppos. no vj. (15 grs. each).

Sig.—One every hour, until relieved

Hemorrhage should be treated by the applica-

tion of cold to the penis. In severe cases a styptic injection, such as a weak solution of the subsulphate of iron, can be used, and in some cases a full-sized sound must be passed into the urethra, and a compress applied around the penis. A moderate amount of hemorrhage should not be restrained as it is more beneficial than otherwise.

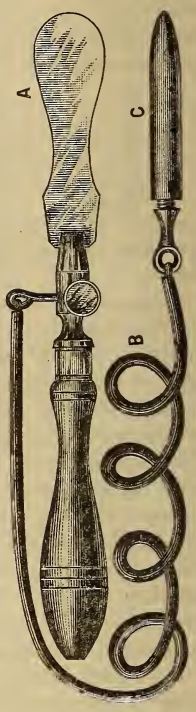
And now, in conclusion, let me advise you to put your patients on good, rich, generous diet, as soon as the acute stage has passed, and if they are at all debilitated, give them tonics, such as the preparations of iron, quinine and strychnia. Also remember that your astringent injections must never be too strong, and that if the little stinging pain they occasion lasts over five minutes, the injection must be diluted, to act well.

Communications.

A SIMPLE GALVANIC ELEMENT FOR THE TREATMENT OF CONSTIPATION.

BY WM. R. D. BLACKWOOD, M.D.,
Physician to St. Mary's Hospital.

Every physician is fully aware of the absolute necessity of a full and free alvine evacuation at least once daily, and he also knows that with very few exceptions a soluble condition of the bowels is of major importance in the conduct toward recovery of his patient, when suffering from disease. It is beginning to be understood that even in those maladies and operations in which the former practice was to lock up the bowel, it is now preferable to maintain a normal state, and simply prevent the diarrhœal effect which may be anticipated. It is most important, in the young, that the habit should be cultivated of attention to regularity in stool, and much of the prevalent dyspeptic tendency is undoubtedly due to neglect of this point. The indiscriminate use of aloetic and mercurial cathartics by the public, in the shape of patent medicines, against constipation, either with or without the sanction of their family attendant, is a growing evil, and should be checked, for much more harm is done in this way than is popularly understood. The canonical method of dealing with constipation presents little breadth in the materia medica employed, and treatment by drugs alone does not often radically *cure*, but merely *alleviates*. In my own practice the best results have been obtained in permanently securing a regular habit through attention to a regular time for defecation—say just after breakfast—combined with faradization and massage of the abdomen. The necessary mechanical or manual part of this process can be taught to the patient, or to the attendant; but the electrical treatment should, except in the case of unusually intelligent patients, be kept in the hands of the physician, for obvious reasons. Those of our readers who are fathers, can doubtless appreciate the trouble caused night after night by the infant, when dirty diapers had been scarce during the day, and how much relief baby had from the use of the old fashioned soap suppository. A recent improvement upon this time-honored instrument is presented in the galvanic suppository, illustrated; and, simple as it is, a somewhat extended experimentation has proved its value beyond a doubt. Although the whole arrangement can be placed in a moderate sized pocket-book, the current developed during its use is equal nearly to that from a small cell $1\frac{1}{2}$ x 1 x 5 inches as determined by a sensitive galvanometer; the current strength being 2 millivebers when in actual use, and nearly 5 millivebers when the elements were placed in a moderately strong saline solution, as, for instance, sodium or ammonium chloride, and the conducting cord replaced by a wire six inches in length. The resistance interposed by the longer cord when in actual use, is so slight as to be disregarded. A simple method of testing the intensity of this little couple is, to insert the zinc negative, or cathode (*C*) into the anterior nares, pushing it up as far toward the frontal sinus as possible without eliciting discomfort, and placing the silver anode (*A*) or positive electrode, upon the tongue, keeping the conducting cord disconnected. Now make and break the circuit, by touching the separated pole with the pin at the free end of the cord, and the flash of light produced by all galvanic applications in this locality, through reflex on the optic nerve, will at once be developed. The current is sufficiently powerful to stimulate intestinal muscular contraction throughout its whole length, and its therapeutic effect is obtained by simply placing the anode upon the tongue and clo-



sing the mouth upon it, the cathode being passed nearly its whole length into the anus, the necessary acidity being supplied by the fluid in the mouth and rectum. In some patients a single application before going to, or while in the closet, for five to fifteen minutes, suffices; in others it should be used at bedtime and in the morning. In very obstinate cases the injection of an ounce or two of salt water into the rectum renders the action more intense, the fluid being retained until the stool is had. Its employment should be maintained for ten days or two weeks, and then gradually discontinued, the strictest attention being, of course, paid to regularity as to visiting the water-closet. That the effect is due to the galvanic current is proved by purposely interposing a non-conducting cord while experimenting, and by substituting plates which do not produce a current. The patients, of course, under these circumstances, were not aware of the defect, and, therefore, the imagination had full play, and the mechanical irritation induced by distention of the sphincters, was also active; yet the result was, in such experiments, uniformly negative. The current may be used in aural practice, by dropping a little salt water into the meatus, and entering the negative rod a short distance therein, the positive being placed upon the tongue. In the earache of childhood this manœuvre has been followed by good results, in a few cases in which it was tried, but the main object is to overcome constipation, and this the miniature battery will assuredly do, with but little perseverance, small expense, and neither trouble nor medicine.

The instrument is neatly made by one of the electrical instrument manufacturers of this city, and the cost is, I am told, quite moderate.

LARGE UTERINE FIBROIDS—HOW TO DEAL WITH THEM.

BY WILLIAM VARIAN, M.D.,
Of Titusville, Pa.

About twelve years ago I developed to my preceptor, the late Washington L. Atlee, the following plan for an operation which I had devised for the destruction of large sub-peritoneal uterine fibromata, which seemed to me to combine efficiency with comparative safety to the patients. The methods hitherto attempted for the extirpation of these adenomata had proved so formidable and fatal as to disincline the profession from adopting them as a common surgical procedure. The time that has since elapsed has added but little to our resources. Normal ovariotomy (Battey's operation) promises much in small tumors, of this class, but how few in private practice can be induced to submit to an operation which is not without its risk, and which carries with it the prospect, repugnant to the female mind, of being unsexed. Immediate extirpation, with or without the uterus and its appendages, had proved so formidable and dangerous, that it was relegated to the place of heroic measures *en dernier resort.* The method which I had devised and carefully elaborated in my mind appeared to me to promise certain destruction of the growth with but little if any more danger than is incurred in laparotomy for normal ovariotomy.

The operation is as follows:—

After the usual primary incision of the abdominal walls through the linea alba, I proposed (*a*) to cut in the line of the original incision, through the capsule of the tumor; (*b*) to enucleate and remove so much of the fibroma as was convenient to the operator, and as could be done without endangering the patient from hemorrhage or shock. The amount thus removed being immaterial, as the taking away of a small portion assured the destruction of the growth as effectually as of a large; (*c*) to include the two incisions in the same sutures, and thus secure agglutination of the peritoneal surfaces; (*d*) after the expiration of a certain time, say from 24 to 72 hours, as the indications demanded, to remove so many of the sutures as were necessary to give free access to the cavity of the capsule; (*e*) by the combined use of therapeutical (ergot) and mechanical measures (the instruments and fingers of the surgeon), to remove the fibroma from day to day, *piecemeal*, as it was loosened and thrust forward by the contraction of the sac; (*f*) when this was accomplished pare the edges and close the external wound.

I claimed that by this course the operator would secure—

1. The shortest possible incision of the peritoneum. No mean advantage, since statistics show that the danger in laparotomy is greatly increased by extending the abdominal incision.

2. Total exclusion of blood or irritating discharges from the abdominal cavity by the early agglutination of the peritoneal surfaces. This reduces the risk of peritonitis to the minimum.

3. Absence of severe hemorrhage, excessive shock, and the necessity of exposing or handling a great extent of peritoneal surface. This avoids the principal factors of danger in all operations for rapid extirpation of these tumors.

4. Facility of access to the tumor. The surgeon has it directly under his eye and can ensure (*a*) The prompt removal of the mass as fast as it

is loosened from its capsule. This anticipates and prevents decomposition. (*b*) Thorough antisepsis, drainage, and, if necessary, irrigation of the sac. This removes almost all risk of septicæmia. (*c*) Perfect control over all tendency to hemorrhage. (*d*) Rapid extraction and removal of the fibroma by the mechanical and therapeutical resources of the surgeon.

I was urged by Dr. Atlee to carry my views into practical effect. He thought that my theory was good, and that it might prove a valuable resource in surgery.

About one year after this conversation I operated in this way upon a case which presented the most unfavorable features. The patient recovered perfectly and her life was prolonged for some years, but I learn that she has since died from an attack of acute pneumonia. An accident destroyed my notes of that case, and it was never published, but I will briefly state that the tumor was very large, adhesions were very numerous and vascular, and the patient was very anæmic, and so prostrated by weakness and pain as to have been confined to her bed for some weeks.

I believe the subject of sufficient importance to warrant the report of a recent case in detail.

Case xxxiv.—Ann R., age forty-seven, unmarried, American, twenty years ago met with an accident while riding a horse, and has been more or less of an invalid ever since. Catamenia first appeared at the age of fifteen, and have always been regular. Since the accident they have recurred every three weeks, and are very profuse during the first forty-eight hours. Are not accompanied with pain. Two years ago she first noticed a central enlargement of the abdomen, which increased more on the right side as it progressed. This growth has been continuous, and during the past six months has been very rapid. There has been a great deal of abdominal pain and soreness, but no history of local or general peritonitis. Her bowels move every day, but a sense of obstruction renders defecation difficult and unsatisfactory. The kidneys have long been in an unsatisfactory condition. The secretion of urine is scanty and she has been accustomed to use stimulant diuretics and gin to increase the flow. Appetite fair. Stomach digests reasonably well. She has œdema of the lower extremities, is anæmic and emaciated, especially about the face and upper portion of the chest. A very large and very elastic tumor fills the abdomen and pelvis. The elasticity is so great as to give a decided sense of fluctuation, which is especially marked when abdomino-vaginal palpation is practiced. The uterus is four inches in depth ; is movable, but does not move with the tumor.

Diagnosis doubtful. Probably, a fibroid. Possibly, an adenoma of the right ovary. The latter was the decision reached by the physician whom she had previously consulted. Patient was anxious for relief by operation, and was placed on treatment preparatory to that end.

Operation.—October 31st, 1881. Present: Doctors Kebler, of Corry ; Blaine, of Pleasantville ; Farrelly and Heath, of Townville ; Moody, Barr, Young, and Reilly, of Titusville.

The strictest antiseptic precautions were observed as regards room, attendants, instruments, and dressings. But the spray was not used. In surgery of the abdominal cavity "fort dem spray" has been my motto ; and a reasonably large experience has not yet given me reason to change my views.

The patient being anæsthetized, the usual abdominal incision was made through the linea alba, about three inches in length. This was afterward extended about two inches upward toward the navel, and one inch downward toward the pubis. The tumor was found to be a fibroid. An incision of five inches, in the line of the external incision, was made through the capsule of the tumor. The capsule was found to be about three lines in thickness over this portion of the tumor. The part immediately presenting was rapidly enucleated, and removed with knife and scissors. At the upper edge of the capsular incision a venous branch was divided somewhat longitudinally, and as it threatened to be troublesome, was secured by a silk ligature, passed through the capsule. It would have been easy to have enucleated and removed a very large portion of this tumor, as the hemorrhage was insignificant, but at this point the patient showed such marked evidences of intolerance of ether that the anæsthetic was withdrawn and the operation was brought to a rapid close.

The wound was closed with ten sutures of silver wire, passed as follows : Through the wall of the abdomen on one side, then through the capsule of the tumor on the same side, and, reversing the direction, out through the capsule and abdominal wall on the other side. By this course, escape of the contents of the sac was prevented, and speedy agglutination of the opposing peritoneal surfaces assured. The external incision was further secured by six superficial sutures of black silk ; the wound dressed antiseptically, and the patient removed to the bed.

Owing to the want of tolerance of the ether,

and so much of the operation being performed during consciousness of the patient, the shock was very great, more marked than in any of my ovariotomies, except one case of sarcoma of the ovary with chronic peritonitis and ascites. Reaction was, however, quite rapidly established, being apparently complete by midnight. The operation occupied about forty minutes, and was completed about 11.30 A.M.

At 6 P.M., the patient vomited, and blood freely oozed from the abdominal incision. I removed three wire sutures from the centre of the incision, cleaned out the sac, and packed it well with styptic cotton. The wound at this point was now left open, but supported by plaster. I was troubled with no more bleeding.

Nov. 1st, 8 A.M. Patient slept well most of the night; pulse 78; respiration 24; temperature normal; reaction fully established; is very cheerful; passed the catheter and obtained ℥ ij of urine, which is all that has been secreted since the operation. 5 P.M. Suppression of urine complete. Ordered pil. digitalis comp., one every two hours; free draughts of infusion of pumpkin seed and flaxseed, with spts. juniperis, as a stimulant; also quinquinia, 3 grains every six hours.

November 2d, 8 A.M. Suppression of urine continues complete; slight evidences of uræmia. Torpor, dullness, and slight jactitation when sleeping. To omit the digitalis pills, and take, every two hours, ℥ j of an infusion of fol. digitalis ʒ ij, fol. buchu ℥ ss, potass. nitratis ʒ ij to the pint. Apply a poultice of digitalis leaves and ground flaxseed to the back; also parvules of calomel, gr. $\frac{1}{20}$, every hour. Pulse 95. Temperature 100.

9 P.M. Got ℥ ij of urine. Patient brighter.

November 3d, 8 A.M. Drew off 8 ounces of urine. To omit the poultices and the calomel parvules; continue the infusion, ℥ j every six hours. During the day the kidneys continue active, and the condition of the patient steadily improves. Uræmic symptoms rapidly disappearing.

November 14th, 8 A.M. Had a good night. Pulse 85 and strong. Temperature 99. Complains of borborygmi and distention of the bowels. I removed, with knife and scissors, several large pieces of the fibroma. From this time until the termination of the case, daily, and sometimes twice a day, I removed the tumor as it was loosened and thrust toward the abdominal opening by contraction of the muscular fibres investing the capsule, in masses varying in amount from a few ounces to three and four pounds at a sitting. The amount removed each morning and evening depended partly upon the facility of removal, but principally upon the tolerance of the patient. I always stopped when she complained of fatigue, no matter how strong was the temptation to continue, as I was determined not to hazard any portion of her small stock of strength through my impatience to dispose of the tumor. The freshly incised surface of the fibroma was always dressed with ferri per sulph., to prevent oozing of blood, together with antiseptics. Until I reached the base of the tumor the bleeding was insignificant in amount; and at no time was there any discharge of pus from the sac. The discharge from the capsule was thin and sanious, small in amount and almost entirely devoid of odor, unless the removal of the loosened portions was too long delayed.

November 5th. Complains so much of flatulence and distention that I order a mixture of cascaris, rhei et senna, and belladonna, which produced three easy movements and gave great relief.

November 10th. An active bilious diarrhœa set in; she had eight motions in the twenty-four hours. None of the evacuations were watery. Kidneys active. I decline to interfere with the catharsis, looking upon it frequently as "critical" in these cases, and to demand interference only when the strength of the patient is impaired by it.

November 12th. Tongue red and dry. Pulse 95. Temperature 101. A good deal of nervous irritation. Bowels moved twice in the twenty-four hours; dejecta loaded with bile. Removed between two and three pounds of the tumor.

November 13th. Condition unchanged. Increase the quinquinia to five grains every six hours. Give ℥ j of port wine every three hours.

November 14th. No improvement; very restless. Pulse 100. Temperature 102. Tongue red, dry, and fissured. Removed over four pounds of the fibroma in the morning and more than two pounds at night. I now learn that, without orders, the nurse had discontinued the use of the sedative during the last four days, and that my patient had been "on her nerve" alone during that time. Ordered thirty drops tinct. opii deod. to be given in a clyster and repeated p. r. n.

November 15th. Patient comfortable. Tongue moist and free from redness. Pulse 90 and firm. Temperature 99. This proves that nervous irritation was the main factor in producing the unfavorable symptoms of the last three days.

But a small portion of the tumor now remains a piece about the size of a small orange being

all that could be disposed of to-day. The blood vessels are larger and tend to free bleeding when severed.

November 16th. Patient feeble and disinclined to take nourishment. Tongue moist, clean, and of a natural color. Ordered beer soup, viz., hot ale or beer, sweetened, with a well beaten egg stirred in. Also rectal alimentation with beef tea, egg, and milk. Removed a portion of the tumor, size of a coffee cup, but the vessels are so large that I resolve to use the écraseur in future.

November 17th. Has rallied well and is comfortable.

November 18th. Still improving. While the patient was on the commode, at 1 P.M., there came a slight gush of blood from the sac, which produced some mental shock. The bleeding was easily controlled by the nurse, who is a woman well suited to emergencies. I surrounded a mass of the tumor as large as the bowl of a goblet with the twisted wire of my écraseur. When nearly severed the wire broke and I was obliged to strangulate the mass with whipcord and sever with the scissors. No hemorrhage.

November 19th. Again strangulated and cut away with the scissors.

November 20th. Several small masses thrown off spontaneously.

November 21st. All that remains of the tumor this day removed. A thick fleshy pedicle is all that remains at the bottom of the sac. Sac walls are so contracted as almost to touch, and are only two inches deep.

November 24th. Patient enjoyed sitting up and eating a good allowance of Thanksgiving turkey and trimmings. Can bear her weight on her feet and take two or three trembling steps.

December 1st. Removed with scissors the thick fleshy pedicle, which alone prevents the closure of the sac. No hemorrhage.

December 5th. Pared the edges of the opening in the abdominal walls and brought them together with silver sutures.

From this time the patient gained daily in health and strength, and on the 20th of December took the cars for her home. Cured.

The estimated weight of the tumor thus destroyed was between twenty and twenty-five pounds.

The above procedure is applicable to all those cases which have reached a size too great to render them amenable to destruction by other medication or Battey's operation. No extent or character of adhesions will interfere with the operation, or endanger the result. It is our duty to attack all fibroids which have attained such size as to destroy the health and comfort and threaten the life of our patient. I claim that I have demonstrated how this can be done with comparatively small risk of failure; and although the course proposed offers nothing specially new, or specially brilliant, but is, on the contrary, slow and plodding, yet if the majority of our patients will get well when thus treated, and a large proportion will die when more heroically and brilliantly handled, let us abandon the desire to display our skill, for the sake of winning the gratitude of our patients by prolonging their lives.

FOWLER'S SOLUTION IN THE TREATMENT OF TETANUS.

BY WILLIAM A. BYRD, M.D.,

Of Quincy, Illinois.

In looking over the late treatises on surgery, I do not find any allusion to the treatment of tetanus by the use of arsenic, in any of its forms; not even in the able addition of Dr. J. S. Jewell to Holmes' System, Am. ed. In a conversation with Dr. John T. Hodgen, last fall, he spoke so highly of the use of Fowler's solution in the treatment of tetanus, that I resolved to put it to the test in the first favorable case that presented. December 5th, 1881, George Schell, a robust laborer, presented himself for treatment. Three weeks before he had received a cut with a stave-shaping machine, on the ring and middle fingers of the right hand, cutting off about half the nail, and last phalanx of the middle finger, and splitting the end of the ring finger for about three-quarters of an inch. He had been under treatment elsewhere, and the fingers were coated with a salve that had shrunken in drying, and had cracked open, curling up at the points of fracture, something like shellac varnish does when applied too thickly to any surface. The wounds were very much irritated, and very painful. The sweat was standing upon his skin in great drops; his tongue was heavily coated with a brownish-yellow, pasty mass; he was unable to open his mouth over a quarter of an inch, on account of pain in the masseter muscles. There was pain of a paroxysmal type along the whole of the back, aggravated by a draft of wind or a touch of one of the affected fingers. This pain was so intense that he would at times fall down and cry out with it. When attacked with one of these paroxysms, his head and heels would be drawn backward, but not enough to call it typical opisthotonos. The first two days I treated the fingers with emollient applications to get off the salve that was constricting them, and gave ten grains of chloral hydrate and fifteen grains of bromide of potassium, every

hour, to allay the pain and to correct the spasm. The appearance of the fingers improved under this treatment, but the general symptoms became worse. I then decided to use Fowler's solution, in large doses, as recommended by Dr. Hodgen, with the exception of giving it by mouth, instead of by hypodermic injection. This I did because there was no irritability of the stomach. He was given ten drops of Fowler's solution, every three hours, for forty-eight hours, and the symptoms closely watched. At the expiration of which time he was so much better that he was given the same amount every six hours. He steadily improved until the 16th, when excessive granulations began to spring up on the wounded surface, on the middle finger, and the nervous symptoms began to reassert themselves. There being no abatement, on the 19th, with the assistance of Dr. G. Connell, I amputated the middle finger at the middle of the first phalanx. All went well until the 22d, when there was found an abscess in the middle of the palm of the hand, requiring to be opened. Upon making the opening there came out a piece of white, swollen, macerated nerve, about one-fourth of an inch in length. When dressing the wound the next day, another piece about the same size came away, and the next day a piece about half an inch in length came away. From this time on he made a speedy and satisfactory recovery. Although amputation had to be resorted to in the end, yet the arsenic exerted so prompt an effect for the better, when chloral and bromide of potassium had failed, that I am satisfied that it deserves all the praise bestowed upon it by Dr. Hodgen, who credits Dr. A. S. Barnes, of St. Louis, with having suggested its use to him many years ago. Any of my readers who desire to read an account of it, written by the doctor himself, will find a very interesting article in the St. Louis *Courier of Medicine*, for December, 1880, p. 519. To Dr. G. W. Connell my thanks are due, for assistance and counsel throughout, in the treatment of this case.

February 10th, 1882.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

SERVICE OF DR. LEVIS.

Reported for the Medical and Surgical Reporter by Richard Douglas, M.D.

Inflammatory Hypertrophy of Legs.

This is one of the most obscure cases that I have ever met. There are certain symptoms connected with the case which indicate the general condition, but do not proclaim a diagnosis. This boy was admitted to the hospital some months since; at that time his condition was about as it is at present, exhibiting the greatest constitutional debility, accompanied by this most peculiar local condition of the lower extremities. The knee joints were enlarged, excessively painful and pitted upon pressure, while the entire surface of the legs was rough and scaly, and the slightest movement gave rise to intense pain. This condition had been developing about two years, and could not be attributed to any special cause. Upon the history and the symptoms presented, after a careful study of the case, the resident surgeon considered it elephantiasis, and has treated the patient for that disease.

First. He has endeavored in every way possible to build up the generally depraved condition of the patient. The local treatment consisted in elevation and support of the limb, and iodine applications were for a time used. Now, while I cannot agree with the doctor in his diagnosis, I certainly indorse his treatment as being the only rational plan that could be pursued. When I first saw the patient, I deemed the end near at hand; but under the supporting treatment life has been prolonged several months, though I cannot see that there is any manifest improvement either in the local or general condition. My reasons for not considering the case *elephantiasis*, are briefly as follows: Elephantiasis is by most pathologists considered an inflammatory disease, affecting chiefly the lymphatics, obstructing their calibre, preventing the return of lymph to the *thoracic duct*, causing an exudation of that fluid, which becoming organized gives rise to great hypertrophy of the cutaneous, subcutaneous, and connective tissue. The vessels become enormously hypertrophied, hence the profuse bleeding attending operations upon structures thus affected. The extremities bear a striking resemblance to the legs and feet of an elephant; hence it takes its name. Such is, briefly stated, the pathology of elephantiasis. You must see how widely it differs from this case. Here we have some enlargement, it is true. The skin, though changed in hue, does not present the hypertrophic characteristics of elephantiasis. Therefore, I do not hesitate to say this is not a case of that nature, though in many points closely resembling it. But, gentlemen, if it is not that disease, what is it? No doubt it is due to some interference with the lymphatics. What that trouble may be, I am unable say. My friend, Dr. Little, of London, England, who is present, may be able to enlighten us.

Dr. Little being called upon, made an examination of the patient, and then addressed the class:—

Gentlemen! To me this is certainly an anomaly. When the case first came in, I at once thought it one of rheumatoid arthritis. But upon learning the history, and by an examination, I have changed my views entirely. It is not rheumatoid arthritis, nor is it elephantiasis. It is a condition too complicated to admit of an easy diagnosis; the great disorganization that has here taken place transcends the limit of almost any one disease. Dr. Levis is no doubt correct in attributing the trouble to the lymphatics. If the general condition of the patient was better, the surgeon would be justifiable in resorting to double amputation.

Five weeks later he was again brought before the class. The following remarks relative to his condition were made by Dr. Levis:—

When this case was before you upon a previous occasion, we found it impossible to arrive at a diagnosis which would warrant us in taking any active measures. He is before you again this morning, and while I cannot see any appreciable change in his general condition, there have been certain local developments which render the pathology clear. This boy is of syphilitic diathesis. I regard this deplorable state the outcome of that disease. You notice the great deformity of the legs; they are both enlarged, out of all proportion, pit upon pressure, are covered with a serous exudation. Should we confine our examination to the lower portion of the limbs we would be at sea for a diagnosis; might possibly call it elephantiasis. We have but to examine the knee joint, and the mystery explodes. You at once notice the great prominence anteriorly. So, likewise, a smaller posterior prominence, which, if examined closely, is found to be, in general contour, much like the head of the tibia, in fact, that is just what it is. The anterior prominence is the lower end of the femur, which, under the action of disease, has become enormously hypertrophied, and then, under muscular and other influences, the tibia has been partially luxated backward. This hypertrophied bone has encroached upon the vessels, especially the lymphatics and veins, occluding their calibre and thus preventing the flow of their contents back into the economy, hence there has been a continued exudation and organization of lymph; in this way the pathology resembles, somewhat, elephantiasis. But here it is dependent upon purely a mechanical cause. There is also, probably, nerve pressure. There is no possible way of obtaining relief, save by resorting to amputation, above the seat of disease; it is true, the patient is in a most deplorable state, but it must be obvious to all present so long as the cause of the disease remains there can be no improvement. Amputation gives the boy a chance for life, and I shall at once submit him to it.

The patient being thoroughly anæsthetized, an Esmarch's bandage is applied to each limb, from the foot up to the middle of the thigh; just here we apply the rubber band; this thoroughly constricts the parts and will enable us to complete the operation without loss of blood. I shall amputate above the junction of the lower with the middle third. It is a matter of small consequence what form of amputation we choose. I generally prefer the antero-posterior flap operation in this locality. The method of procedure is as follows: Grasping the limb about the centre of its circumference, with the left hand, and fixing the thumb and index finger at opposite points, as guides, with a long scalpel in the right hand, I make a curvilinear incision from point to point. The curve, of course, must be directed with its convexity downward, and will vary in accordance with the desired length of the anterior flap. I always prefer a long flap anteriorly, and a proportionately short one posteriorly. This first incision must extend down through the superficial parts to the muscles. This flap, consisting of cutaneous and connective tissue, is dissected back about three-fourths of its length. We then, with a circular sweep of the knife, divide the muscles at this point, thus cutting through the vessels transversely. The bone is next sawed through. The stump is dressed in the ordinary manner, and after washing out all clots and debris with carbolized water, with a Davidson syringe, the operation is complete. Both limbs were treated in the same manner.

Infra-Maxillary Neuralgia.

This woman, aged seventy years, is a great sufferer from neuralgia in the infra-maxillary region. You are aware that all tissues of the body, in the old, undergo somewhat of a retrograde metamorphosis. The vessels take on calcareous or fatty degeneration. The muscles become attenuated; the intimate structure of the bones is changed; they lose, to a certain extent, their animal constituents; the lacunæ and canaliculi are obliterated by the deposit of earthy salts; thus they are deprived of their vitality, become fragile, and are rendered liable to disease and injury. These senile changes are, perhaps, more manifest in the inferior maxillary than in any other bone. You know the greater portion of that bone is composed of soft, cancellous structure, with large alveoli for the reception of the teeth. In the old the teeth fall out, the alveoli become obliterated and the bone shrinks in size. The canals through which the minute branches of the dental nerve ramify, becoming partially obliterated, the terminal filaments of the nerves are pressed upon, giving rise to intense suffering. The neuralgia attending organic lesion to the nerve itself, or arising from the pathological condition referred to, is constant in character, and differs markedly from the intermittent form of the disease depending upon malarial or other influences. Organic neuralgia (so to speak) for a long time baffled the skill of the profession, but within the last quarter of a century it has been found a cure can only be effected by a complete excision of the nerve affected; this operation has been practiced by many, to quite a bold extent, and has been frequently followed by miraculous results. I have performed it in quite a number of rare cases, with most satisfactory results, but have always met with one great difficulty, the tendency of the divided nerve to unite, and thus establish the same old trouble. In exsection of nerve trunks, I have not only removed some portion of the cord, but have taken the precaution to turn the divided ends back into the muscular tissue, hoping in this way to cut off all possible chance of reunion; but even in these cases I have been surprised, in cutting down upon the part, later, to find the divided ends had come together. Therefore, I repeat, in order that the operation may be followed by permanent cure, complete excision of the affected cord is required. One year ago this old woman came under my care suffering with infra-maxillary neuralgia. I decided to excise the affected nerve, and performed the operation as follows: A curvilinear incision, about two inches in length, with convexity downward, was carried over the ramus of the jaw; the flaps thus made were dissected up, the bone laid bare, the trephine applied, and a disk of bone was removed, the dental vessels

and nerves exposed in their canal; the nerve was raised on a hook, and pulling backward, about one inch of it broke off in the canal and was cut away. The parts being washed thoroughly with carbolized water, the flaps were brought into close approximation, the ordinary dressing applied, and the operation completed. The wound healed by first intention, and for ten months the patient was entirely free from neuralgia. Two months ago the trouble returned. She is here to-day, in the hope of again obtaining relief. There is no doubt in my mind, that new nerve tissue has been formed to supply the gap made by the excision one year ago, and the impression made upon the sensory filaments is conducted uninterruptedly back along the cord. I shall to-day perform a more thorough excision ; attempt to expose the nerve at its entrance into the dental foramen, and remove the entire portion lying in the canal. The infra-maxillary nerve makes its exit from the skull through the foramen ovale, and enters the inferior maxillary bone on the inner surface about one inch below the sigmoid notch, one inch and a quarter above the angle, and a quarter of an inch anterior to the posterior border of the ramus. Now, I wish to expose the nerve just above this point, as it lies upon the bone before entering the foramen. In order to reach it we would ordinarily apply the trephine. To-day I propose using the dental or surgical engine, as it is called. This engine, an ingenious invention of Dr. Bonwill, a dentist of this city, has proven of much value to the surgeon in operations upon bones. The feature of the instrument consists in a spindle, which, by means of a somewhat complex arrangement of wheels, is made to revolve many thousand times per minute; to this spindle you can attach the instrument most desirable for the purpose to be accomplished. For the operation of trephining, Dr. J. B. Roberts has modified the ordinary burr used by the dentist, and has fashioned a burr which presents two cutting surfaces, one on the flat end and the other on the circumference. It strikes me that this is particularly well adapted for trephining. Commence by making a groove with the edge, and as it cuts its way we turn the flat end directly down upon the bone; we are thus enabled to perforate the bone in much less time than is ordinarily required in manipulating the ordinary trephine. The advantage of having the cutting edge upon the circumference is, that by means of it we are enabled to enlarge the opening laterally to any desired extent. I shall apply it to this bone, and you will see how excellently it serves our purpose. Having removed a circular portion of bone, about one-third of an inch in diameter, I now enlarge the hole laterally and search for the dental nerve. Our calculations were correct; here it is, exposed, just at the foramen; grasping the nerve with my forceps, I pull it out from the canal, with my scissors cut away this portion (about two inches in length). The approximal end I stretch well, a procedure I think of much value in all operations upon nerves. You notice, gentlemen, there is a rupture of a small artery. This will not require ligation; the hemorrhage is readily controlled by pressure with the hand in the mouth, or by plugging the hole with sponge. Having removed all debris, cleansed the part thoroughly with carbolized water, and adjusted the flap by silver sutures, the operation is complete.

WESTERN PENNSYLVANIA HOSPITAL, PITTSBURGH, PA.

Reported by V. Kersey, Resident.

Three Cases of Tetanus.

Case. 1.—Wm. McF., aged 35, single, a moulder by occupation, of temperate habits, with history of previous good health, was admitted to this hospital, May 29th, 1881, with a crush of the right hand. The hand was run over by the wheels of a passenger railway car, and the palmar portion and all the fingers except the proximal phalanx of the index, and the thumb, were crushed. The integument of the palm retained its connection with that of the forearm by a slender pedicle of integument.

Dr. C. B. King decided to make an attempt to save the hand. The fragments of phalanges were removed, the extremities of the bones rounded off, with bone-pliers, and a few sutures of fine silver wire introduced. The hand was then enveloped in warm cloths, and grain ¼ of morphia sulph. administered hypodermically.

June 1st. The palmar flap is of a very dark color, and a distinctly gangrenous odor is observed. The hot applications are continued. Temperature and pulse normal.

Upon June 4th, the flap was dead, and was clipped away with scissors. Patient complains of stiffness and pain on opening the mouth. Was ordered gr. xx of chloral hydrate, every third hour.

June 5th. Marked rigidity of muscles of posterior-cervical region; complains of headache and lumbar pains; bowels open; takes liquid nourishment freely. The jaws cannot be separated further than one-fourth of an inch.

A secondary amputation of the member was decided upon. This was performed, by the flap method, at the middle of the forearm. Vessels secured by torsion, and dry dressing applied.

June 6th. Rigidity increases; lies upon his side, with head thrown far back, and trunk arched forward ; had two or three mild exacerbations of rigidity, succeeding paroxysms of coughing.

During these increases of rigidity the breath came hard between the set teeth, the respirations were shallow and irregular, and he complained of pain. Increased chloral to gr. xxx, every two hours. The patient had no more well marked spasms than those described above, but the general rigidity steadily increased. The jaws became inseparably locked at about 3 P.M., and continued so until his death. The death occurred at 3.30 A.M., June 7th, nine days after receipt of injury, and five days after onset of tetanic symptoms.

Case 2.—Benjamin F. C., aged 18, single, brakeman, of temperate habits and previous good health, was admitted June 21st, 1881. This man had suffered, twenty-five minutes before admission, a crush of the right lower extremity to within six inches of the trochanter major, a loaded car or two having passed over the limb. Within one hour of the time of receiving the injury the member was amputated by Dr. James

McCann. After securing, by ligature, the femoral vessels, in the wound, lateral flaps were formed and the bone sawn across, about three inches from the trochanter major.

The wound was closed by silver wire sutures, a dressing of resin cerate and dry absorbent cotton was applied. External heat was applied, and half a fluid ounce of whisky, with thirty minims of aromatic spirits of ammonia was administered every two hours.

June 23d. Some gastric irritability being present, the stimulants were withdrawn, and the amount of beef tea and milk was increased. The bowels moved freely, and patient is quite rational.

June 26th. The stump was examined to-day for the first time; the edges were adherent throughout most of the extent, though at two points small superficial sloughs appeared. Complained of pain and stiffness in the jaws. The brow was corrugated; the sterno-cleido-mastoid muscles were abnormally prominent and tense. Ordered grs. xxx of potassium bromide, every third hour; also a large, hot poultice of flaxseed meal to envelope the stump.

June 27th. The rigidity of the muscles steadily increased, extending to the abdominal and dorsal, and muscles of arm and forearm. He had no convulsions. During the last few hours of life he was unable to separate the jaws enough to admit the ingestion of anything in the shape of food or medicine. He died quietly, six days after receipt of injury, and forty hours after onset of symptoms.

Examination of stump after death showed, 1. Large, bulbous and congested end of sciatic nerve. 2. The branches of the anterior crural, and the trunk of the sciatic were ecchymosed and softened. The vessels presented no features worthy of note.

Case 3.—Wm. F., aged twenty-three, single, brakeman, of temperate habits, with no history of previous injury or sickness, was admitted, September 13th, 1881, with the following history: Four days ago he was coupling cars, and had the index and second finger of the left hand crushed between the "drawheads." The second finger was amputated at once, but efforts were made to save the index finger.

When admitted to the hospital, he had recived no attention, except that bestowed at the time he received his injury. The finger, when divested of the dressings, was found to be in a state of gangrene. Hot flaxseed meal poultice was applied and patient placed in bed. The next day Dr. J. B. Murdoch ordered the hand to be placed in a hot water bath, except at night, when it was to be placed in cloths wrung out of hot water.

September 19th. A line of demarcation having been formed, the finger was amputated at the metacarpo-phalangeal articulation, wound closed by silver wire sutures, and dressed with dry absorbent cotton. In ten days (September 29th) the stump of index finger was healed, and that of the second finger nearly so.

October 1st. The stump of index finger has a small abscess upon one side, which was opened to-day; a small amount of sanious pus escaped.

October 3d. Stump of second finger healed; abscess on stump of index finger nearly closed.

October 4th. Patient has been up and about the ward for past eight or ten days. Complains, to-day, of stiffness and soreness of the muscles of jaws, neck and back. Pain on mastication and deglutition, and on attempting to bend the trunk. He was ordered to bed, and a hot poultice placed about the entire hand. Gave him grains x of chloral hydrate and grains xx of potassium bromide, every three hours.

October 9th. Complains of moments of smothering, during which he is compelled to sit erect in bed to get his breath. Jaws are rigid; cannot be separated wider than a quarter of an inch. Mental faculties are dull. Owing to the fact that he had not been sleeping well, he received one grain of powdered opium, and in two hours the dose was repeated. He got no sleep, however. The bowels were maintained in a loose state, by daily administration of comp. cathartic pills.

October 11th. By order of Dr. Murdoch, the hand was immersed in the continuous hot-water bath (105° Fahr.). Dose of chloral and of bromide increased, the former to xx grains, the latter, to grains xl.

October 16th. The rigidity has almost entirely disappeared. Patient sleeps very well, and time between doses of bromide and chloral is lengthened from three to four hours. Bowels are freely moved every day.

October 23d. Removed the hand from water bath, and allowed the patient to get up and move about, within doors.

It is now nineteen days since the symptoms and signs of tetanus were noticed in this case.

November 26th. During past four weeks the patient has received no medicine, except an occasional purge.

November 28th. He is discharged cured.

In connection with the foregoing cases, the following points are considered worthy of note: 1. Absence of a well-marked convulsion. 2. Absence of fever. 3. The difference in treatment.

Abortion Without Pain or Hemorrhage.

Dr. William Girdner, of Greenville, Tenn., relates the following unique case in the *Medical Gazette*, November 26th, 1881:—

Martha G., aged twenty-seven years; married; multipara; pregnant about nine weeks. About six o'clock on the morning of October 20th, when entering the dairy door, it fell from its hinges, and knocked her to the ground. She got up, feel ng no injury, and went about her household duties as usual.

About five o'clock the same afternoon, when in the act of micturition, a fœtus dropped from her, about the size of a small mouse, the act being wholly unattended by pain or hemorrhage.

About three hours later the secundines came away without hemorrhage, and with only a slight trace of pain. I saw her on the 22d of October, two days after the abortion, and she expressed herself as well as usual. There has been no discharge of any kind from the vagina to indicate rupture of the attachments of the contents of the impregnated uterus, nor have pain or any other symptoms been present as evidence of this interference with the physiological process of gestation.

Periscope.

Filaria Sanguinis Hominis.

From the London *Lancet* we note that in the twenty-first issue of the Chinese Customs Medical Reports, Dr. Myers records some further interesting observations concerning the filaria sanguinis hominis, made in the island of Formosa. It seems that although this island is only separated from the main land, where filaria disease abounds, by a channel 180 miles wide, three cases only of elephantoid disease have presented themselves in nine years among 15,000 general hospital patients, and the three filaria infested persons Dr. Myers saw all came from the main land (Amoy and district). This fact, that the disease does not spread in the island, as Manson conjectured it might have done into Barbadoes, is the more remarkable, as communication with the main land is constant, and there is an abundance of mosquitoes, so that Dr. Myers surmises that the particular species of mosquito which is the true intermediary host of the filaria exists on the main land, and probably not on the island. He is at present carrying out a systematic investigation of the different species of mosquito. First, Dr. Myers put a conveniently willing and infected man to sleep in a gauze-covered mosquito house, into which he turned mosquitoes collected promiscuously from all parts of Formosa. These gorged insects he examined day by day, and found that the next morning after their feed they contained several lively embryos, which at later date became digested, and had evidently not got into their true host, for Manson has found that mosquitoes containing filaria sanguinis hominis, when fed on an infected dog, digested the filariæ of the latter. Secondly, Dr. Myers has also made some observations on the periodicity of the appearance and disappearance of the filariæ embryos in respect of the blood circulation, in the case of a man suffering from glandular swellings and recurrent lymphatic fever, but otherwise healthy. The tables given show a result in complete accord with Manson's observations. The embryos appeared in the blood circulation regularly between 6 P.M. and 8 P.M., generally a little after 6 P.M., and were present in greatest numbers about midnight, after which they gradually decreased, and pretty well disappeared by 6 A.M. to 8 A.M. This period of twelve hours is just the time that, as Manson has shown, the mosquito is in active search for food. Thirdly, Dr. Myers tries to make out what becomes of the embryos when they disappear from the blood circulation, whether this disappearance is final as regards the swarm, and caused by death, or whether they only lie dormant for the time, perhaps in some viscera, as the lungs. He made prolonged and careful observations on the condition of the embryos at the times of their appearance in the circulation and their disappearance, and he found that the most marked and unmistakable contrast existed between their excessively active, vigorous condition at the former time and their increasingly torpid and feeble, shriveled, straightened out state at the latter time. He thinks the disappearance is final as regards the swarm, and he further argues that unless the parent or parents breed only once, or at long intervals, the circulation would get almost blocked by the myraids of filariæ if there were not some more wholesale method of removal than mosquito sucking. Dr. Myers suggests the possibility of the diurnal solution of dead embryos. Fourthly, Dr. Myers watched the behavior of the embryos with such substances as bisulphate of quinine, salicylic acid, arsenious acid, and santonin. The quinine affected them most, but the upshot of the matter is that the quantity of any of these substances necessary to kill the embryos would kill the host also. The problem, therefore, seems to be how to diagnose the exact situation of the parent worm (generally lying in the superficial glands) with an accuracy sufficient to extract it.

Cardiac Hypertrophy and Renal Disease.

Apropos of this interesting subject the *Lancet* says:—

The problem of the subordination of cardiac hypertrophy to renal disease, when the two coexist, to which so much discussion has been lately devoted, has engaged the attention of M. Straus, of Paris, who has published in the *Gazette Médicale* a preliminary account of his experimental results. The difficulties of the problem of the relation of the heart to the kidney lesion depend upon the complexity of the morbid conditions present in the system. These are much simplified in an experimental inquiry, although the results thus obtained have not always been very decisive. It is difficult to preserve for long the life of animals after a lesion of both kidneys, and Straus has therefore contented himself with causing atrophy of one kidney by ligature of the ureter. Previous experiments of the same kind have yielded contradictory results. Simon, Rosenstein, and Gadden, observed no cardiac consequence; Beckmann, Grawitz and Israel, and Lewinsky found a resulting hypertrophy of the left ventricle. The experiments of Straus were made on twenty guinea pigs, which were killed from four to six months after the operation. A pure hypertrophy of the left ventricle was found to be the invariable result. The average weight of the heart, for instance, in three cases was 2.76 grams, while that of three healthy animals was only 2.25 grams, and this although the average weight of the guinea pigs operated upon was two hundred grams less than that of those selected for comparison. The hypertrophy was uncomplicated by any degeneration of the muscular substance of the heart, and was apparently the direct result of the atrophy of the kidney, since the arterioles in various parts were examined and

found to be healthy. Grawitz and Israel asserted that although cardiac hypertrophy might follow a renal lesion in old animals, in which the other kidney did not sufficiently overgrow to compensate for the loss, this result was not to be obtained in young animals. This statement is disposed of by the experiments of Straus, since nearly all the guinea-pigs he experimented upon were young. Moreover, he was unable to observe any inverse relation between the degree of hypertrophy in the heart and kidney, such as should obtain if the conclusions of Grawitz and Israel were correct. In one of the cases in which the increase in weight of the heart was greatest, the remaining kidney had increased to at least double the normal weight. An objection which is often urged against the dependence of cardiac hypertrophy on renal disease is the absence of such hypertrophy in cases in which the kidney suffers in consequence of an affection of the urinary passages. But Straus relates, to show that hypertrophy may be found in these forms, two cases of women dying from uterine cancer which had compressed the ureters, and had caused dilatation of the pelves of the kidneys and very marked renal lesions. In each there was considerable hypertrophy of the heart without any valvular lesion. In a discussion on this paper at the Société de Biologie, an interesting and apposite case was related by Quinquaud. A man of twenty-eight years of age was shot in the left lumbar region, and recovered after an illness attended with hæmaturia. At this time there was no hypertrophy of the heart, but distinct evidence of this was discovered two years afterward. He died with symptoms of uræmia four years later. The left kidney contained an old abscess, the right was hypertrophied, and the heart was increased in weight to eighteen ounces, in consequence of hypertrophy of the left ventricle. All the liquids of the body were found to contain a large excess of urea.

A Case of Rupture of the Bladder.

T. J. Call, M.D., M.R.C.P. Edin., contributes to the London *Lancet* the following case:—

J. R., a chimney-sweep, between fifty and sixty years of age, had for a long series of years suffered from stricture of the urethra, through which, and only by dint of coaxing, a No. 3 was the largest size of catheter which could be passed. Although this stricture was the cause of frequent complete retention of urine, and at the best of times water could only be passed through it in a very feeble stream, he would not consent to have any operation performed for its relief, nor would he attend with sufficient regularity to have it gradually dilated. He was content to go on as he had been doing for over twenty years, and to present himself in the out-patients' room once in every week or two, in order to have his bladder relieved.

One afternoon I happened to be passing his house when his wife called me in. I found him walking about the room, evidently in great pain, with no other clothing on than his shirt, and his bladder enormously distended; as, according to his usual custom, though repeatedly cautioned against it, he had, in the hope of being able to relieve himself, been drinking freely of gin and spirits of nitre ever since the morning, when the retention had begun. Not having a catheter with me, I told him I would obtain one, and come again. As his house was only about five minutes' walk from the Infirmary, I should be back to him within a quarter of an hour from the time of my first seeing him. I now found him in bed, entirely free from pain, and the floor of the room swimming with water. On asking what had happened he told me, and his wife confirmed what he said, that while walking about, the water suddenly, and without the slightest warning, came, in one great gush, through the anus. That something of the sort must have occurred was evident from the fact that it would have taken more time than I had been absent for the large amount of urine to have dribbled through the stricture; besides, there was both his own and his wife's testimony to the fact, and there was no reason why they should deceive me. Fearful of the consequences of urinary infiltration, I enjoined perfect rest; but the next morning I found him going about as usual, quite well, and voiding urine in the manner to which he had been so long accustomed.

Just one week after this I was asked to visit him, and again found him suffering from retention. This time, however, I was unable to pass the catheter, and, as he was suffering frightful pain, I got Dr. Easton, one of the visiting surgeons to the Infirmary, to see the case with me. Together we were unable to introduce any, even the smallest, instrument into the bladder, though we overcame the stricture so far that the urine began to flow and give him relief. Little over a week and again he presented himself in the out-patients' room, this time to have the catheter passed without the slightest difficulty; and ever after, so long as he remained under my observation, the operation was easily performed.

I may add that, from first to last, I was never able to detect any enlargement of the prostate. The interesting points in this case are the rupture without any infiltration of the cellular tissue, and the rapidity and completeness with which the rent had healed so as to withstand every effort to empty his bladder made by a powerful, muscular man.

Can a Man have Syphilis Twice?

The *British Medical Journal* reports the following valuable remarks by Mr. Jonathan Hutchinson, on this interesting topic:—

The man whom we have just seen offers a remarkable example of the occurrence of a second chancre soon after the first. His second sore has been, as I have repeatedly demonstrated, characteristically indurated. He is quite candid, and makes no doubt that this sore was the result of contagion. Yet it is barely a year since he had his first chancre, and this was followed by an eruption, of which he had scarcely got clear when this second sore occurred. The case is proof that a man may have an indurated sore on the penis within a year of a former one, but it is not proof that he may have syphilis twice, for this patient has not as yet had any constitutional symptoms as the result of the last chancre. If,

however, you ask me for an answer to the general question, Can a man have true, complete syphilis twice? then I must reply clearly that he can. Such cases are rare—as rare, perhaps, as examples of second attacks of smallpox—but they do occur. I am at present attending a gentleman who has a terrible phagedenic chancre and rupial eruption, and who unquestionably had complete syphilis, chancre, sore-throat, and rash, seven years ago. I have also a second case under care, very much milder, but illustrating exactly the same fact, with almost precisely similar dates. Second chancres are, however, far more common than second attacks of constitutional syphilis. Many of them are the result of fresh contagion, but seem to have no power to produce constitutional symptoms; but others are not from contagion at all, but form in connection with a taint still remaining from the first attack. It is a most important fact that indurations may form in the penis, in every respect exactly like Hunterian chancres, not distinguishable in any way, and yet they may be merely recurred sores, and the products of constitutional taint. I have seen this over and over again; and M. Alfred Fournier, of the St. Louis Hospital, has written a very instructive paper on this form of sore. In the case of our patient, it is obviously impossible to say, after the statement which I have just made, whether or not his present sore is the result of fresh contagion. It may simply be a relapse, or it may be a gumma. He, however, confesses to exposure; and, as the sore followed in due course, it is probably true that he was afresh inoculated. Second attacks of syphilis are sometimes, as in the case just mentioned, very severe. The same has, I believe, been occasionally noted in recurred attacks of variola. As a rule, however, they are mild, or even abortive. Third attacks may even occur; and so may, as we are told, third attacks of smallpox. We must explain such facts, I expect, by reference to individual peculiarity and idiosyncracy, but it is important that they should be known. The belief that syphilis can occur but once in a lifetime is very widely spread among a certain class of the public. I have watched with amusement the change in expression in many a young gentleman's face when he got my reply to his smiling suggestion—"A man cannot, I suppose, have the disease a second time?"

Case of Incised Wound of the Skull; Trephining; Recovery.

Dr. Edward Cotterell reports the following interesting case in the London *Lancet*:—

The patient, aged twenty-one, was thrown from his dog cart, striking his head on a pile of stones. He was seen about three-quarters of an hour after the accident, when he was found, totally unconscious, and suffering from concussion, with some signs of compression. Upon examining his head, I found an incised wound of the scalp in the left temporal region, about two inches and a half long from before back, and on introducing the finger there could be felt an incised wound of the skull about one inch long.

I determined that trephining ought to be done, as there was undoubtedly depression of the inner table of the skull. I performed the operation at once, and on raising the circle of bone cut by the trephine, a loose piece of bone, an inch long and half an inch wide, consisting of the inner table, was seen lying on the dura mater. This was easily taken away through the trephine hole, and consciousness was almost immediately restored. The wound was left quite open, a piece of lint dipped in carbolic lotion being placed over it. The next morning an ice bag was applied to the head and five grains of calomel put on the tongue; later in the day a copious enema was given, with good result. The following is a record of the temperature and pulse: July 10th, 11 A.M., temperature 99°, pulse 60; 3 P.M., temperature 101.2°; 7 P.M., temperature 100.7°, pulse 64; 11 P.M., temperature 101.2°. July 11th, 3 A.M., temperature 101°; 7 A.M., temperature 100.7; 11 A.M., temperature 100.8°; pulse 64; 3 P.M., temperature 99.8°; 7 P.M., temperature 100°; 11 P.M., temperature 100.6°; July 12th, 3 A.M., temperature 99°; 7 A.M., temperature 98.6°; 11 A.M., temperature 99.2°; pulse 60; 3 P.M., temperature 98.4°; 7 P.M., temperature 98°; pulse 48; 11 P.M., temperature 98.4°. July 13th, 3 A.M., temperature 98°; 7 A.M., temperature 98°; 11 A.M., temperature 98.6; pulse 56; 3 P.M., temperature 98.2°; 7 P.M., temperature 98.2°; 11 P.M. 99°. Temperature ever since has remained perfectly normal.

July 11th. Patient had a rather restless night, but toward morning slept well. In the afternoon slept well. July 12th. On visiting the patient this evening the pulse was found to be only 48, very soft and compressible. The whole condition of the patient indicated profound weakness. A mixture was prescribed containing some carbonate of ammonia and chloroform, which appears to have acted very well, as the pulse the next morning rose to 56, and the day after to 64.

The wound healed by granulation, and was perfectly closed by August 7th, one month after receipt of injury. As will be seen, the patient never had a bad symptom after the operation, a result very seldom seen in these serious head injuries. On October 1st, after a holiday at the seaside, the patient resumed his business, and now does not seem any worse for his accident, except that he suffers occasionally from neuralgic pains at the seat of injury.

Wound of Left Lung—An Extraordinary Case.

Dr. L. E. Homles reports the following remarkable case in the London *Lancet*. A miner, aged 31 years, was standing at the bottom of a mining shaft 225 feet deep, when a drill, three feet one inch long, one inch and a quarter in diameter at the bit, and weighing eight and a half pounds, fell from the top. The patient was standing with his shoulders slightly dropped forward. The bit of the drill struck him between the superior angle of the left scapula and the spine, about two inches from the latter, passing downward and forward near the left border of the heart, and emerging at a point on a line with the left nipple and six inches from the centre of the sternum, fracturing the sixth rib, making a wound eight and a half inches in length. The drill passed nearly through, the head seeming to

the man to remain in the region of the left armpit; the point emerging struck the ground, bringing the man to the ground, upon his face. The patient called upon one of the men standing near him to assist in drawing out the head of the drill, and both pulling together succeeded in doing so. The head was much battered, and must have torn the lung and flesh considerably in passing through.

On entering the hospital the patient was bleeding freely, and in a fainting condition. Air, at each expiration, passed with a gush of blood from both ends of the wound. Hæmostatics, consisting of gallic acid and ergot, with stimulants, were freely administered, and the opening temporarily sealed. The bleeding ceased rapidly, but the patient recovered slowly from the shock. Sixteen days after the injury he was able to walk about. He remained in the hospital eight weeks, when he considered himself sufficiently recovered to go to his private boarding house to remain. The wound, or wounds, for it had two open ends, began to discharge matter on the fourth or fifth day, which was very offensive, and became very abundant. For three or four days, once a day, injections of carbolic acid (ten drops to the ounce) were made through the track of the wound, with a common Davidson's syringe. These, feeling disagreeable to the patient, were discontinued, and simple dressings used once or twice daily. The offensive character of the pus soon changed, though the abundance continued for several weeks. The lung has shrunken to about two-thirds its natural size. The respiration at the time of leaving the hospital was 28, and the pulse 90. The wounds ceased to discharge fifty-one days after the accident, and closed, except the lower one, which, with no perceptible opening, merely moistens the dressing during the night. Since leaving the hospital the patient has gained much flesh, and says he feels nearly as strong as ever. There was never any marked pleurisy, and no great amount of fever at any time during his stay in the hospital.

Uræmic Convulsions Treated by Vapor Baths and Chloral—Recovery.

Dr. A. B. Keely reports this interesting case in the *Lancet*. The patient, a lady, aged thirty-seven, thought she was suffering from a bilious attack. Examination revealed the following symptoms: Suppression of urine, with intense headache, nausea and constant vomiting, frequent pulse, and hot, dry skin. She had not passed water for a week. Bowels very constipated. She was ordered a mixture of acetate of potash, spirit of nitrous ether, chloric ether, and water, to be taken every four hours. He also ordered a vapor bath by means of a spirit lamp placed under a cane chair, a blanket being over the patient and a couple of aperient pills, containing colocynth and blue mass, at bedtime. By the next day, neither aperient nor diuretic had acted. The intervals between the diuretic were lessened and the baths given every three hours. Regular vapor baths were subsequently resorted to, because the patient was unable to get out of bed. After the first one, copious diaphoresis occurred, but no urine was voided. The next day uræmic convulsions set in and continued, throughout the day, to grow more and more severe, until on the subsequent morning they were so violent as to render the vapor baths impossible. She was then given one drachm of syrup of chloral and five grains of iodide of potassium in one ounce of water, every three hours. After the first dose the convulsions ceased. The chloral was therefore stopped, but the iodide was continued. Half a drachm of compound jalap powder had no effect on the bowels. This dose was repeated four times, but did not act until an enema was given, and then only slightly. She now voided about one half pint of urine, the first in fourteen days. Vapor baths were now given every three hours, each one acting well on the skin. She was nourished with milk and beef tea. One grain of elaterium in a little sugar produced one good evacuation from the bowels. From this time out the patient passed water two or three times daily. The urine contained two-thirds albumen. She now complained of great pain in the loins, over the kidneys. Hot fomentations gave her great relief, and she passed a considerable quantity of water during the next twelve hours. The baths were continued for three weeks, being gradually reduced in frequency during the day: the iodide was continued for the same length of time. At the end of three weeks from the beginning of her illness the patient was able to be moved to a sofa. Her bowels acted daily, without any aperient. During convalescence meat and fish were given on alternate days, together with such vegetables as marrow and beans. About a quart of milk was taken daily. At the end of a month the patient was able to walk about, when she was removed to the country, where she gained strength rapidly. When the solid food was begun, fifteen minim doses of the perchloride of iron were substituted for the iodide. The attack was attributed to a cold.

Pathology of Hydrophobia.

At a recent meeting of the Microscopical Section of the Manchester Medical Society, reported in the *British Medical Journal*, Mr. E. H. Howlett exhibited some sections of the spinal cord from a case of hydrophobia. After briefly alluding to a series of cases of hydrophobia, in which four out of five persons bitten by the same rabid dog had died with well marked symptoms, he proceeded to discuss the pathology of the disease by stating that, for a long time, the virus had been known to exist in the saliva of rabid animals. Microscopical examination of saliva would naturally demonstrate the presence of numerous organisms, but such a result was to be expected even in the saliva of healthy individuals. With the view of ascertaining whether any particular form of disease could be discovered in the salivary glands themselves or in the blood, the following experiment was performed. Within an hour and a-half of death, portions of the submaxillary, parotid, and sublingual glands, with Stenson's duct, were dropped into test-tubes containing a fine turnip infusion; also the same organs were placed in some dry test-tubes, and the whole series placed in an incubator, where they were kept for several weeks. These

test-tubes were exhibited to the Society (eight months after the commencement of the experiment), and it was seen that the solutions remained perfectly bright and clear; and, of the dry preparations, with the exception of the one containing parotid gland, no change beyond the drying up of the tissue occurred. From these results, it was concluded that no organism existed in the salivary glands or blood in hydrophobia which was capable of causing any form of fermentative change. Microscopical examination of the other organs failed to demonstrate the presence of any micro-organism.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Transactions of the Medical Association of Georgia, Thirty-second Annual Session, 1881, comes to us from the Secretary, A. Sibley Campbell, M.D., as a handsome cloth-bound volume, of three hundred pages, well illustrated and containing much of interest.

——Photographic Illustrations of Cutaneous Syphilis. By George Henry Fox, A.M., M.D. New York: E. B. Treat, No. 757 Broadway. We have before us parts 10, 11, 12, of this most admirable series. The price is two dollars per part. They are well worth it, to all who can afford it. The illustrations are so realistic that they almost make one shudder; they remind us of the impressions made upon entering the chamber of criminals in Madame Tussaud's wax works establishment in London, where the representations of noted criminals are so natural and life-like as to be startling. These illustrations are so *beautifully* natural as to be horribly perfect.

——We have received from Messrs. G. P. Putnam's Sons, publishers, of New York, a circular, to the effect that the rumored sale or discontinuance of the *Journal of Nervous and Mental Diseases* has no foundation in fact. The journal will be published by them hereafter, as it has been in the past, under the editorial management of Dr. W. J. Morton, of New York City, assisted by Drs. Jewell (the former editor) Seguin, Hammond, Bannister, Clymer and Ott.

BOOK NOTICES.

Opium Smoking in America and China. By H. H. Kane, M.D., author of "Drugs that Enslave," etc. pp. 156. New York: G. P. Putnam's Sons, 1882. For sale in Philadelphia, by J. B. Lippincott & Co.

Dr. Kane possesses unusual facilities for familiarizing himself with the questions about which he treats. He is connected with a home for the cure of the opium habit, and has studied and written much on the subject. The author is a pleasing and instructive writer, and his book contains much that will be of interest to the physician. This habit of using opium as an intoxicant is, according to Dr. Kane, becoming frightfully prevalent in our country, so that in a few years it will constitute one of the evils with which sociologists will be compelled to make warfare. It behooves all who may directly or indirectly have any influence over the private life of others to read this book, that they may understand and be prepared to intelligently grapple with this growing social evil.

Illustrations of Dissections, in a Series of Original Colored Plates, the size of Life, representing the Dissection of the Human Body. By George Viner Ellis, Professor of Anatomy in University College, London, and G. H. Ford, Esq. pp. 233. New York: William Wood & Co. 1882.

This volume constitutes the January number of Wood's Library. It is one of the most interesting and valuable books that have been issued in this library, containing, as it does, a very large number of colored plates, reduced, on a uniform scale, from drawings from nature. An explanatory text accompanies each plate. This volume is well calculated to refresh the knowledge of anatomy acquired in the dissecting-room, and will be a useful addition to every physician's library.

Fistula, Hæmorrhoids, Painful Ulcers, Stricture, Frolapsus, and other diseases of the Rectum; their Diagnosis and Treatment. By William Allingham, Fellow of the Royal College of Surgeons of England, Surgeon to St. Mark's Hospital for Fistula and other Diseases of the Rectum, etc., etc. Fourth Edition. pp. 492. Price, $3.00. Philadelphia: Presley Blakiston, 1882.

This a valuable and practical work. Its practical nature is guaranteed by the opportunities for observation enjoyed by its author. Its value and popularity are attested by the sale of three large editions, and by its translation into French, Italian, Spanish and Russian. The literary tendency of the times is toward the production of volumes on special diseases and accidents, and it is necessary that this should be so. Since, in this age of unparalleled progress in everything, medicine and surgery participate, and hold their own, the accumulating information concerning different deranged conditions is becoming so extensive that it would be impossible for any text-book, however large and cumbersome, to contain all that is important and interesting. Therefore, these special volumes, when emanating from competent authors, are to be wel-

comed, and the one under consideration, we can truthfully say, possesses much interest for the general practitioner. It is well illustrated.

A Treatise on Human Physiology; designed for the use of Students and Practitioners of Medicine. By John C. Dalton, M.D., Professor of Physiology, and Hygiene in the College of Physicians and Surgeons, New York. pp. 792. Philaphia: Henry C. Lea's Son & Co. 1882.

It is only necessary to announce this new (seventh) edition of this standard work on Physiology, and to state that it has been thoroughly revised, so as to bring it up to the standard of the present time.

Diseases of Women, including their Pathology, Causation, Symptoms, Diagnosis and Treatment. A Manual for Students and Practitioners. By Arthur W. Edis, M.D. Lond., F.R.C.P., M.R.C.S., Assistant Obstetric Physician to the Middlesex Hospital, etc., etc. pp. 576. Philadelphia: Henry C. Lea's Son & Co. 1882.

We have so many good books on the diseases of women, that it seems almost needless to prepare any more for some time, until we have made such advances in this branch of medicine as to make the present volumes old and behind the age. Still, when a man who possesses opportunities for observation prepares a book, we may always be sure that we will find something instructive and interesting in it. The author of this work has had such opportunities, and we can commend his book to all physicians who have not on their shelves a recent standard work on diseases of women. The work is well illustrated.

The Sympathetic Diseases of the Eye. By Ludwig Mauthner, M.D., Royal Professor in the University of Vienna. Translated from the German by Warren Webster, M.D., Surgeon U. S. Army, and James A. Spalding, M.D., Member of the American Ophthalmological Society, etc. pp. 220. New York: William Wood & Co., 1881.

This is a valuable work, intended to bring familiarly before the general practitioner the important knowledge concerning sympathetic diseases of the eye. It is written in an interesting and intelligible style, and with a degree of force that carries conviction. When an author of eminence announces, in italicized words, "*When the other eye is in a state of irritation, an eye which still possesses vision must be unhesitatingly sacrificed*, success is too certain, and too much is at stake for the oculist to hesitate," we are led to conclude that he must have had great experience, else his edicts would be less positive. This will be found a very useful book by the general practitioner.

The International Encyclopædia of Surgery; a Systematic Treatise on the Theory and Practice of Surgery. By authors of various nations. Edited by John Ashhurst, Jr., M.D. Six vols. Vol. I, pp. 717. New York: Wm. Wood & Co.

This is a very valuable volume, prepared by gentlemen of universal reputation. The section on "Disturbances of Nutrition; the Pathology of Inflammation," is by S. Stricker, M.D., Professor of Experimental and General Pathology in the University of Vienna. "Inflammation," by Professor W. H. Van Buren, of New York. "Erysipelas," by Professor Alfred Stillé, of Philadelphia. "Pyæmia and Allied Conditions," by Francis Delafield, M.D., of New York. "Hydrophobia and Rabies; Glanders; Malignant Pustule," by William S. Forbes, M.D., Demonstrator of Anatomy, Jefferson Medical College, Philadelphia. "Scrofula and Tubercle," by Henry Trentham Butlin, Demonstrator of Surgery at St. Bartholomew's Hospital, London. "Rachitis," by J. Lewis Smith, M.D., Clinical Professor of Diseases of Children in Bellevue Medical College. "Scurvy," by Phillip S. Wales, M.D., Surgeon General U. S. Navy. "The Reciprocal Effects of Constitutional Conditions and Injuries," by A. Verneuil, M.D., Professor of Clinical Surgery in the Faculty of Medicine, Paris. "General Principles of Surgical Diagnosis," by Professor D. Hayes Agnew. "Shock," by C. W. Mansell Moullin, M.D., Surgical Registrar to the London Hospital. "Traumatic Delirium and Delirium Tremens," by William Hunt, M.D., of Philadelphia. "Anæsthetics and Anæsthesia," by Professor Henry M. Lyman, of Chicago. "Operative Surgery in General," by John H. Brinton, M.D., Lecturer on Operative Surgery in Jefferson Medical College, Philadelphia. "Minor Surgery," by Charles T. Hunter, M.D., Demonstrator of Anatomy in the University of Pennsylvania. "Plastic Surgery," by Christopher Johnston, M.D., Emeritus Professor of Surgery in the University of Maryland. "Amputations," by John Ashhurst, Jr., M.D., Professor of Clinical Surgery in the University of Pennsylvania. This synopsis of contents is the best way to notice this volume. The reader can, from it, form an idea of the scope and nature of the work. In these progressive days, encyclopædias are necessary to those who would desire to keep abreast of the times, and more particularly to those physicians who, living far away from large cities, are thereby denied the privileges of hospital instruction.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

ETHICS COMMON TO PHYSICIANS AND PHARMACISTS.

It is of unquestioned importance, both to pharmacists and physicians, that the relations existing between them should be amicable and honorable. There can be no doubt but that all the worthy members of both these avocations earnestly desire such to be the case. Grievances have long existed which are not yet settled, and it requires a careful consideration of the equities of both sides to arrange entirely harmonious relations. The physician must not insist on steps which, if carried into effect, would depreciate the business interests of the druggist; and the latter ought not to insist on privileges which are detrimental to the physician. Both should recognize that the public and the general mass of society have claims which should not be overlooked.

These themes have been weighed conscientiously, by prominent members of both professions, and, as one of the results, we may name the unanimous adoption of a Code of Ethics by the Pennsylvania Pharmaceutical Association, at its last annual meeting, in June. Several of its sections pertain directly to the relations of pharmacists to physicians, and we believe that readers both in and out of this State will be glad to peruse them, and we, therefore, quote them, from the *American Journal of Pharmacy*:—

II. Although not a legitimate part of our business, custom and the necessity of the times warrant us in keeping the proprietary medicines of the day; yet, out of regard to the medical profession, and for the protection of the public, we earnestly recommend all pharmacists, when called upon for an opinion of their merits, to discourage their use, and neither to advertise nor permit their names to be used in advertising such medicines.

III. Recognizing the value of alcohol as a therapeutic agent, and the propriety of its being dispensed as such by pharmacists, yet deploring the wide-spread evil resulting from its indiscriminate use in its hundred insidious forms, we condemn any attempt to make it a prominent feature of our business, as unprofessional; and we denounce the loose practice of allowing it to be used on the premises, in any shape, as a beverage, as degrading, and we urge upon pharmacists the duty of exercising a conscientious care in dispensing a drug liable to such dangerous abuse.

IV. We discountenance all secret formulas between physicians and pharmacists, and consider it our duty to communicate such to one another, when requested.

V. We distinctly repudiate the practice of allowing physicians a percentage on their prescriptions, as derogatory to both professions.

VI. We will endeavor, as far as it lies in our power, to refrain from compromising the professional reputation of physicians, and we expect the same comity from them.

VII. Since the professional training of the pharmacist does not include those branches which enable the physician to diagnose and treat disease, we should in all practicable cases decline to give medical advice, and refer the applicant to a regular practitioner.

The remaining sections pertain to matters which have less interest for the medical profession, and we omit them.

There are two points in this Code to which we would particularly call the attention of physicians, because, if they are not carried out, it is the physicians who will be wholly to blame. These are the practice of secret formulas between physicians and druggists, and the acceptance by physicians of percentages from druggists. It is vain for some to say that these practices are unknown, or are very unusual. We know to the contrary, and we could name members of the medical profession in this city, of a certain degree of eminence, who do not hesitate to stoop to both these practices. They would not dare

to come forward and defend them, but they continue to make money out of them.

It would be well, and we suggest it here, that the members of every regular medical society individually sign a resolution declaring such practices dishonorable and denouncing those who persist in them. We have grave doubts whether all of the members of the medical societies in this city would sign such a paper; but if they do not, the reason would be obvious, and they should be censured. If we want the druggists to act according to the code of honor, why this tergiversation on our part? Why hesitate to put ourselves square on the record?

We predict, however, that although this course is so clear and open, it will not be taken. There are influences of too strong a kind against it; and the time has not yet come when even men holding official positions in the profession in this city are free from the questionable methods of financial "kiting" we have named.

INOCULATION.

In these days of unparalleled progress in everything, suggestions of all kinds are admissible, since nothing seems impossible of achievement. Our science fully holds its own in this march of progression, and is making rapid strides toward a firm scientific basis.

It becomes the duty of medical journalists to suggest to original medical investigators hitherto unexplored paths, and to encourage them to work in these directions.

Since it has been vouchsafed to us to discover a method by which the ravages of smallpox may be stayed, why, we would ask, cannot further investigation enable us to extend this protective immunity to all the contagious diseases. It is generally conceded that vaccination confers immunity from smallpox by destroying or altering some of the conditions of the blood necessary for the development of the disease. Why cannot these same effects be produced in connection with the other zymotic diseases. If, let us suppose, a person in health were to receive into the body some of the poison of typhoid fever, measles, scarlet fever, or diphtheria, might it not be that this poison could, without producing a dangerous disease, so modify and alter or destroy the conditions or elements upon which or from which this disease in its more virlulent form is developed as to render the subsequent occurrence of a severe and fatal attack as rare as in the case of smallpox. Might not this poison, introduced into a system not yet ripe for it, where it would find the conditions necessary for the full development of the particular disease, yet have such an effect on these elements or conditions, whatever they may be, that they would never after be capable of uniting with the poison and producing the disease in its aggravated form. These few words are given as a hint; we would invite discussion on the subject.

Notes and Comments.

Physiological Effects of Prolonged Bathing.

In an investigation on the above subject, published in *Paris Médical*, for December, and giving a very accurate account of the effects which baths produce on the system, according to their duration and temperature, Dr. Théry has arrived at a number of conclusions which are both interesting and true. He says: A bath at 97° Fahrenheit is without effect on the circulation. All baths below 97° reduce the action of the heart. The beats, however, acquire greater energy. The pulse retains perfect regularity. Circulation is not reduced in direct ratio with the temperature of the water, but it is influenced by the duration of the bath.

When baths at 75° or less are prolonged for an hour, arterial pulsation continues decreasing after exit from the water. Baths at or below the temperature of the body quicken circulation. This acceleration is proportional to the temperature of the water. The pulse is irregular and the heart fluttering.

Baths between 97° and 99° are without effect on animal heat. Baths below 97° reduce the temperature of the body. Baths between 92° and 97° cause a loss of 0.97° to 1.46°; this reduction is obtained within half an hour; after this the thermometer remains stationary, even should the bath be continued for two hours.

In baths at 86° or under the fall in temperature is more gradual; it is in proportion to the duration of the bath.

The first effect of a bath at 72° or less causes

a slight elevation of temperature. The fall in temperature obtained by means of a half hour bath at 93° is almost equal to that produced by a bath at 72° continued for an hour. After a bath above 82°, continued for an hour or two, temperature has an upward tendency, although for the following twelve hours it remains from 0.5° to 1° below what it was before the bath. After a bath under 81°, the thermometer continues falling during the next twenty minutes following exit. During the twelve hours following a prolonged bath, at from 64° to 81°, the thermometer indicates a reduction of 1° to 1.50° from the initial temperature.

All baths at or above the temperature of the body produce a rise in central temperature. The rise, in proportion to the temperature of the water, is progressive. A bath at 108°, continued for nineteen minutes, raises the temperature of the body to 104°. A bath at 68° progressively raised to 95° produces a fall in temperature. A bath at 97° gradually reduced to 75° causes, as a first effect, a fall in temperature; but subsequently, in proportion as the temperature of the bath decreases, that of the body rises. It is only between 91° and 97° that baths can be continued for a long time without causing suffering.

In water, the sensation of cold acts by reflex action, first on the smooth muscular fibres, and later on the striated.

Hot baths predispose to syncope; they are followed by profuse perspiration.

All baths, when long continued, are debilitating.

Elongation of the Lingual Nerve.

At a meeting of the Société de Chirurgie, reported in *Le Progrés Médical*, M. Ledentu presented a woman upon whom he had performed an elongation of the lingual nerve, in a case of tic douloureux of the face and epileptiform neuralgia of five years' standing. Having no positive data as to the tractile force that should be applied, and mindful of the accidents which have sometimes attended the elongation of cranial nerves, M. Ledentu, after exposing the nerve, took it up on a hook and carefully raised it only about four lines above the buccal floor; he then allowed it to drop in the wound, where it assumed an S shape. Immediate relief followed, and for thirteen days past the patient had not experienced any of her former excruciating pains. Will this condition continue? In the debate that ensued M. Auger asked if the lingual nerve had a red and inflamed appearance, that having been his own experience in a case in which he had lately operated. M. Ledentu replied that the nerve was normal, both in form and color. M. Polaillon believed the cure would be a permanent one; he had performed a similar operation, some three months before, and the patient was doing well. M. Nicaise spoke of the dangers incident to elongations of cranial nerves. In conclusion, M. Tillaux mentioned a case of a purulent flow of the eye in a patient upon whom he had performed a resection of the upper maxillary nerve. This accident, he believed, was due to the nerve section. The patient, for the last four years, had been doing remarkably well.

The Treatment of Scarlatina.

In an article published in *Le Concours Médical*, Dr. Paul Gerne, makes the following suggestions for the treatment of scarlatina. He says:—

We shall not here attempt to decide on the prophylactic and curative merits of belladonna; we will only say that experiments made for that purpose have given widely divergent results. If it is desired to use this remedy, the following is a good formula:—

℞. Ext. belladonna, 0.15 c. = gr.ii¼
Distilled water, 30 gm. = ʒ viiss
Alcohol, rectified, 1 " = ♏xv. M.

Of this mixture, give as many drops, morning and evening, as there are years in the patient's age.

In regular and normal forms of the disease the treatment should be purely hygienic; the patient must be kept in bed, in a room having a temperature of from 64° to 68°, F.

The patient should not be surfeited with warm drinks; he may have reasonable quantities of lemonade, to which wine can be added, when there are symptoms of weakness.

Until the period of desquamation is reached, the food should consist of broth, unless otherwise specially indicated.

The infectious nature of the disease warrants the use, as recommended by Scott, of an aqueous solution of sulpho-phenate of soda, in doses of from 0.30 centigr. to 1 gram (= grs. ivss—xv.) In irregular forms, the predominating symptoms, will, of course, indicate the particular measures that should be adopted. The hyperthermia in those ataxic forms rapidly accompanied by serious nervous, comatose, convulsive, or dyspnœic symptoms, is successfully checked by cold lotions and affusions, and in very severe cases, cold baths may even be given.

As an anti-thermic remedy, we use sulphate of quinine; but salicylate of soda should never be

displayed, because it might superinduce nephritis, which is always imminent, or aggravate it, if already present.

In syncopal forms, wine, alcohol, cinchona and digitalis, are to be exhibited.

In gastro-intestinal forms (complicated from the start by incoercible vomiting and profuse and persistent diarrhœa), opiates are to be used, also Seltzer water, and ice in small pieces be frequently given by the mouth.

We will conclude with a few remarks on the experiments made by Dr. Demme, of Berne, with *pilocarpine*. According to him, in scarlatina, when the exanthema is retarded, excellent results may be derived from the diaphoretic effects of pilocarpine, and the serious nervous symptoms usually occurring in such cases may be averted. But this medication, even when displayed at the outset of the eruptive period, is powerless in preventing renal complications. By stimulating diaphoresis, it may lessen the gravity of the uræmic symptoms, which frequently happen during the period of decrease. But the use of this remedy requires the greatest caution; its depressive action upon the heart, when given in rather high doses, predisposes to collapse, and this danger is almost constantly impending, after the use, during a few days, of hypodermic injections of one-sixth of a grain of chlorhydrate of pilocarpine. Dr. Demme, therefore, recommends that this remedy should only be administered in limited doses, and that its use be preceded by cordials, generous wines, or strong infusions of coffee or tea.

The Purity of Chloroform.

While even perfect purity in chloroform is not an absolute safeguard against accidents, it is of sufficient importance to deserve the attention of every surgeon; hence the following easy tests, recommended by Professor Regnauld, and published in *Le Progrés Médical*, will no doubt be read with interest.

1st. Chloroform should have an agreeable odor.

2d. It should not redden blue litmus paper.

3d. Added to a solution of nitrate of silver, it should neither give a precipitate, nor even cause cloudiness.

4th. It should not become colored, when brought to the boiling point, along with a concentrated solution of caustic potash.

5th. Sulphuric acid should not blacken when brought in contact with chloroform.

The above tests are not difficult; besides these, there are others, such as determining the *specific gravity* and the *boiling point*, which, however, are more within the province of a chemist; but no chloroform should ever be used for anæsthetic purposes which does not comply with the above requirements.

Chloroform, even when perfectly pure, is liable to sudden changes. Exposure to light, an imperfect cork stopper, or a but partially filled bottle, are conditions which may affect its purity; hence it should be occasionally tested, especially before using. Dr. Yvon, is of opinion that the sulphuric acid test is not fully reliable; on the other hand, as caustic alkalies are used for the purpose of rectifying chloroform, there may be circumstances when the absence of coloration with an alkaline solution is not positive evidence of purity; he, therefore, recommends, as a far more delicate test, the combined action of permanganate of potash and a caustic alkali.

As a reagent, he uses a solution of:—

℞.	Permanganate of potash,	gr. xv
	Caustic potash,	ʒ iiss
	Distilled water,	ʒ viiss.

This solution is of a handsome violet-red color, and when in contact with *pure chloroform*, remains unchanged. But if the chloroform has been *imperfectly* rectified, the solution is acted upon, and its color gradually changes to green.

To be successful, this test requires considerable nicety.

Syphilis from Epidermic Grafting.

In the *Progrés Médical*, we notice that at a meeting of the Société Médical des Hôpitaux, M. Fèréol reported the following, case observed by M. Debel: A man, 49 years old, was under treatment for gangrenous erysipelas, and extensive ulcerations, the cicatrization of which was progressing with great difficulty. M. Debel applied 45 dermo epidermic grafts on the external half of the sore. 33 of these were successful. A few days later, a number of other grafts, taken from different individuals, were applied to the internal half of the ulceration. Not long after cicatrization was progressing favorably, but there appeared on the sore an ulceration of the size of a twenty-cent piece, having a grayish-white color, which went on increasing, and presently overspread the untire ulceration.

After a time, mucous patches appeared in the mouth, and roseola over the skin. The presence of syphilis was unmistakable. Upon investigation, the attending physician found that the patient's son, from whom some of the grafts had been taken, was suffering from syphilis. In this case specific treatment was found useful, and under its influence cicatrization of the sore was successfully accomplished.

A Remarkable Wound of the Brain.

The *Lancet* for January, 1882, reports the following wonderful case, which was presented to the Société de Médicine de Paris by M. Dubrisay. A man determined on suicide held in his left hand a dagger, about 3⅓ inches long and ⅓ of an inch wide, and placing the point against his skull, struck it several blows with a mallet, believing that he would fall dead at the first blow. To his surprise he felt no pain, and observed no phenomena. He struck the dagger, in all, about a dozen times. When seen, the handle of the dagger was projecting from the skull at the junction of the posterior and middle third, a little to the right of the middle line, and in a transverse position. All of the blade except one-third of an inch was imbedded. The most strenuous efforts were made to remove the dagger, without avail, so tightly was it held in position. Neither did these efforts cause any pain. The man then *walked* to a coppersmith's, where he was fastened to rings fixed in the ground, and by strong pincers the handle of the dagger was fastened to a chain, which was placed over a cylinder turned by steam power. At the second turn the dagger came out. The patient, during all this time, suffered no pain or inconvenience, and in a few minutes *walked* to a hospital, where he remained in bed for ten days, but without fever or pain. He then returned to his work, and the wound gradually healed. By driving the dagger into the head of a cadaver in the same situation and to the same depth, M. Dubrisay found that, without injuring the superior longitudinal sinus, it had passed into the cerebral substance, just behind the ascending parietal convolutions, and thus behind the motor zone; the point had not reached the base.

Diabetes Insipidus Treated by Electricity.

Dr. C. P. B. Clubbe speaks of this method of treating diabetes, in the London *Lancet*. He reports the case of a woman who passed from eighteen to twenty pints of urine per diem. It was light colored, very low specific gravity, and contained no sugar. All the drugs recommended for diabetes were tried, without result. She was then ordered electricity (faradaism), to be applied over the region of her kidneys every day, for about twenty minutes at a time. Under this treatment the daily average amount of urine diminished during six weeks, from 237 to 113 ounces; where it remained nearly stationary, varying but little. At the end of the twentieth week all treatment was discontinued. Six months afterwards she was in about the same condition as when treatment was stopped. Dr. Clubbe thinks this result would justify the more extended use of this treatment in diabetes insipidus.

Traumatic Tetanus—Recovery.

Dr. H. J. Lloyd reports the following case of traumatic tetanus which terminated in recovery, in the London *Lancet*. The patient, six years old, had his hand lacerated. The wounds healed satisfactorily. Two weeks subsequently tetanic symptoms set in. The disease was well marked and characteristic in every symptom. The treatment adopted was to open the bowels with a brisk purgative of calomel and scammony, application of ice to the spine, and after the bowels were well moved, three grains of hydrate of chloral were given every hour, until sleep was produced, then every four hours, as long as rigidity of the muscles continued. The patient was kept up with beef tea and mutton broth. The bowels were kept open with the purgative powder occasionally. In three days the spasms gradually disappeared, and the patient was quite well in a month.

A New Bougie.

In the *Transactions* of the Mississippi Medical Association, Dr. Daniel reports two cases where, after having failed to pass the smallest bougie through a stricture of the urethra, he resorted to a small fiddle string, which readily passed the obstruction. After remaining in situ a few minutes, it was found, upon withdrawal, to have swollen to nearly double its original size. A larger string was passed, and after remaining ten or fifteen minutes, was withdrawn, when the urethra was found to be sufficiently dilated to allow the passage of a No. 4 bougie.

A Grain of Corn Discharged Through the Chest.

Dr. S. Wilks reported an interesting case to the Pathological Society of London (London *Lancet*). The patient (a child) was suffering from an abscess over the left supra-scapular region, the skin over it feeling boggy. A grooved needle was passed in, and a puff of air and pus came out. Free suppuration occurred, and after a time a grain of corn was passed, and then the wound healed. No other cause being found for its presence, it seemed that the grain of corn must have been inspired into the lung.

Chlorosis Treated by Chlorhydric Acid.

In the *Centralblatt für die Med. Wissensch.*, Dr. Zander contests the somewhat generally accepted opinion, that chlorosis is developed by a deficiency of iron in the alimentation. He believes that food always contains a sufficient quantity of iron, but its absorption is often imperfect, because the digestive juices are of faulty composition, and more especially, owing to the fact that the gastric juice lacks its necessary proportion of chlorhydric acid. As an attending consequence, the albuminoid principles are but imperfectly digested, hence, languid nutrition also follows.

Acting upon this theory, Dr. Zander has treated chlorosis by the aid of chlorhydric acid, giving it according to the following formula:—

℞. Chlorhydric acid, f℥ ss–j
Distilled water, f℥ vj. M.
One or two tablespoonfuls after each meal.

In very stubborn cases, he has added artificial pepsine to the chlorhydric acid. The results have always proved highly satisfactory.

Ergotine in Pharyngitis.

The *Revue Mensuelle de Laryngologie*, indicates a therapeutic method which may give good results in cases of chronic pharyngitis, complicated by exaggerated enlargement of the pharyngeal veins, and muco purulent secretions. It advises the use of—

℞. Ergotine, gr. xv
Tincture of iodine, ℥ j
Glycerine, f℥ viiss. M.

To be liberally applied, twice a day, on the pharynx, by means of a brush.

Special Reports.

NO. III—INFECTIOUS DISEASES (Continued.)

In examining the literature of the past year, we fail to find any progress worthy of special note in the domain of etiology and treatment of the infectious diseases, beyond those already recorded with reference to diphtheria. We have great reason to hope, and this hope is encouraged by the valuable researches and discoveries of M. Pasteur and of other workers in the same field, that the day is not far distant when we will possess accurate knowledge concerning the causative agency of the various infectious diseases.

It is from research in this direction that we must, in an especial manner, look for the grounds upon which to base a rational and successful therapeutic course. Clinical research has been and is, a very valuable aid to therapeutics; indeed, most of the existing knowledge we have to-day concerning the treatment of disease, has been derived solely from clinical observation. But, without desiring to detract from this valuable factor, we must recognize that it is very much like working in the dark, so far as discovering a specific for the poison of the infectious diseases. We all admit our inability to control, cut short, or abort a case of typhoid fever, of measles, of scarlet fever, and the like. We can only treat collateral symptoms as they may arise, support the patient and wait until the special poison has expended its force, the disease has run its course, and hope for a successful termination.

If some original investigator can exactly determine the nature of the special animal or vegetable growth which, when introduced into the system, is capable of giving rise to any of these zymotic diseases, a great step towards a special therapeutics of this disease has been made. If, then, he can produce this growth artificially, outside of the body, a great stride has been made, and he has, most likely, within his possession the necessary elements out of which to evolve a *specific* for this disease.

If, as we suppose, the development of the zymotic diseases is due to the presence and activity of some foreign living elements in the system, it would seem to be a rational conclusion that if the life of these foreign elements could be destroyed, the disease would not be developed, it could be aborted.

Therefore, when some investigator has succeeded in artificially developing the disease germs, he can take them into his chemical laboratory, and by repeated experiments may finally be enabled to decide upon some drug capable of destroying their vitality. It will then remain for extended clinical research to demonstrate whether or not this parasiticide will still retain its destructive power when it meets the organisms in the system, surrounded and influenced, as they must be, by the conditions they find therein.

This would seem to be the course indicated by which we may hope to ultimately discover some remedy through the potency of which we may be enabled to abort these diseases in their incipiency. We trust and pray that before many years have gone by we may have the extreme pleasure of recording some such results. The example set us by M. Pasteur is in the right direction, and it behooves some of our energetic American physicians to follow in his footsteps, and endeavor to

surpass him, so that this wonderful discovery may emanate from our wonderful country.

During the past year more attention has been given to the means of preventing the ravages of the infectious diseases, both by disseminating information touching on the prophylaxis and by public and concerted measures. The Contagious Diseases Act in Great Britain has been productive of very much good. Inspector ANNISS stated, in the London *Lancet*, that under the working of this act the ravages of infectious diseases had very much diminished. Formerly cases of smallpox and scarlet fever might exist in brothels, quite unknown to the authorities, and thus the infection might be communicated to a large number of persons. Under the present system such a case could not remain unnoticed by him on his visits, and he would order the brothel keepers at once to send the patient to the hospital, and to have the rooms properly disinfected; otherwise, he would take measures to have the house placed "*out of bounds*," that soldiers and sailors should receive strict orders not to enter it. Realizing, as we do, the importance of isolation in staying the ravages of infectious diseases, we are prepared to appreciate the wisdom of this provision of the act.

It is a matter of paramount importance that physicians should thoroughly realize and should instruct the public that the evil habit of suppressing the existence of infectious diseases, lest their known presence may injuriously affect the commerce of a locality, is very strongly calculated to favor the continuance and increase of these diseases. It is a wrong and fatal idea, and should be corrected. Realizing this point, the Sanitary Council of the Mississippi Valley passed the following resolution:—

Resolved, That this Council condemns all methods of suppression and secrecy with reference to information of contagious or infectious diseases; therefore it discountenances the use of *cipher* telegrams; but in the event of danger from such diseases at any point in the Mississippi Valley, it is the duty of the executive officer of the health organization of such place to fully and promptly advise the proper authorities at all threatened points.

This is a point that is entirely too much neglected. When we must realize that isolation is one of the most potent (and in many cases the most powerful) means of circumscribing infectious epidemics, we must admit and teach that it is the first duty and a most conscientious one, for all physicians, as well as the public press, to give full notoriety to any cases of infectious diseases that may exist in a locality, in order that the health authorities and the public may be roused from their lethargy and stirred into instituting proper and efficient isolative and disinfective measures.

From the *National Board of Health Bulletin*, we note that a sanitary examination of the city of Memphis, subsequent to the fearful epidemic of yellow fever which prevailed there in 1878, exhibited the following condition. The death rate for three years previous to 1878 was 35 per 1000; for the first yellow fever year 114 per 1000, and for the last 51 per 1000. Within the city limits were found six thousand sub surface cesspools in use. They were, in many instances, shallow holes, with no lining. Many of them were in dangerous proximity to dwelling rooms, some of them being actually excavated in the cellars of occupied dwellings. There were also a large number of disused but *full* vaults, the contents of which, in some cases, were entirely uncovered, while in the majority there was only a thin layer of ashes. Nearly all the cisterns and wells that supplied water to the inhabitants were situated sufficiently near to these vaults to be contaminated by their leakage. Is it any wonder that this terrible epidemic prevailed? Ought we not rather to be surprised that it spared any one? This terrible state of affairs was intelligently remedied, and as a result, Memphis has been comparatively free from disease.

The *Mississippi Valley Medical Monthly* gives some statistics that demonstrate more clearly than words how possible it is to limit the infectious diseases, and how beneficial have been the intelligent sanitary improvements carried out in Memphis. From them we learn that the decrease in deaths from zymotic diseases during 1881, as compared with 1880, was, in Memphis 0.73; in Cincinnati only 0.48; in Chicago 1.12; while in New York the increase was 2.06; in Brooklyn 1.65; and in Philadelphia 2.68. Philadelphia has of late years been a very dirty city.

During the first quarter of 1880, the death rate in Memphis from diarrhœal diseases was 1.19 per 1000; for the same period of 1881 it was 0.59, a decrease of fifty per cent. Many valuable lessons in the limitation of infectious diseases can be derived from the sad experience of disease stricken Memphis, and its subsequent restoration on sound sanitary principles; lessons that teach us that we have, to a great extent, in our hands the sure means of saving many lives annually that are now prematurely sacrificed on the altar of infection.

(*To be Continued.*)

Correspondence.

Penetrating Gunshot Wound of Brain.

Ed. Med. and Surg. Reporter:—

In your issue of January 28th, 1882, is an article from the Boston *Medical and Surgical Journal*, by Dr. J. Foster Bush, giving the details of a case of penetrating gunshot wound of the brain, so similar in locality and course of the ball, but so very different in effects to one that came under my care when a surgeon in the Confederate army, that I feel it is worthy of publicity.

Private J. B. C., of the Twelfth Tennessee Regiment of Confederate Volunteer Infantry, while on picket duty in front of our army, at Corinth, Miss., May, 1862, standing behind a tree, in the act of taking aim at one of the enemy, also on picket duty, head protruding, received a ball from what was supposed to be a Maynard rifle, of about forty calibre, one and one-half inches above the left eye. He said, "I fell, dropping my gun, very much stunned, but soon recovered enough to regain my gun, and with it and other equipage, walked to camp (distant two miles). Seated in a chair in front of my tent, I examined his wound, finding it located as above stated, with quite an amount of blood on and around the wound, coagulated, and with the coagulated blood was as much as a tablespoonful of brain; he seemed to be perfectly rational; said he had not lost very much blood; pulse and general appearance did not indicate that he had; did not complain of much pain; had neither paralysis, loss of sensation, nor aberration of vision. On examining the wound it was found to be large enough to admit the little finger to the second joint. The aperture in the skull was remarkably smooth, having but a few small spiculæ; the ball passed directly inward and backward (no other probe than the finger was used in the examination), but did not pass out, and consequently remained in the cerebral cavity. The wound was cleansed and dressed with a wet compress and bandage, and he sent to the hospital, three miles in the rear, in the town of Corinth. I learned that he had high fever on the third or fourth night, and was delirious. In a few days the evacuation of Corinth took place, preventing my seeing or hearing anything from him for some six weeks or two months, when he surprised me very much by returning and reporting to his command for duty, in as good health, he said, as he ever was. The only thing to indicate that he had had a serious wound, was a scar and marked depression in the bone. He continued in good health, on active duty, making the campaign into Kentucky, with Bragg, in midsummer, returning about the first of October, at which time he became subject to epileptoid seizures, which gradually developed into well defined epilepsy, for which he was discharged in February, 1863. Mr. C. was in my office two or three months ago, in fine health. Says his "fits" have gradually become lighter, and do not now give him much inconvenience; and his father, in the last few days, said "he did not think he had them at all now."

Trenton, Tenn., February, 1882.

The Spread of Smallpox.

Ed. Med. and Surg. Reporter:—

I have read with great interest your article on the "Spread of Smallpox." There is one form of contagion, however, that I do not find noticed very frequently in medical journals, viz: the contagion emanating from the rag-rooms of paper mills. During the last ten years, fully three-fourths of the smallpox cases I have attended occurred among employés in the paper mills, chiefly those engaged in sorting rags. The cases were most prevalent in those mills where domestic rags were used. I remember but few cases in those mills where imported rags were used, which, I have been informed, are very thoroughly disinfected before they are received at the mills.

While on the subject of smallpox, I would like to call attention to the question of the identity of variola and varicella. Although the majority of the profession do not believe in this identity, yet, during the last few years, several cases have come under my care which would seem to make me doubt whether the two diseases may not be one and the same. During November, 1879, I was called to see two children, a boy and a girl, aged, respectively, 12 and 14 years, who had high fever, pain in the back, and many of the prodromes of variola. They proved to be severe cases of varicella. During the convalescence of these children, they were visited by a girl, aged about 15 years. Ten days subsequently she was seized with the same symptoms, but the disease turned out to be variola, a malignant case, severe epistaxis and metrorrhagia being among the grave symptoms. Death occurred at the end of the sixth day. During the last four years a number of similar cases have occurred in my practice. It may be said in regard to the first cases that they were light cases of varioloid. Surely a light case of varioloid and a severe one of varicella are scarcely distinguishable from each other. I do not argue, from the few cases I have observed, that variola and varicella are identical, but merely submit these few remarks to the attention of the medical profession, in the hope of eliciting discussion, and probably throwing further light upon what I think may be considered a very important question.

Ross R. Bunting, M.D.

Roxborough, Pa., Feb'y 9th, 1882.

Congenital Dislocation of Tibia.

Ed. Med. and Surg. Reporter:—

I was called last November to see a child some four hours old. I found the leg dislocated backward into the popliteal space and at a right angle with the femur. The midwife said the child was born head first. I reduced the dislocation with very little effort, when the knee seemed perfect in conformation. I applied a splint. At the end of two days, I removed the dressing, and found the joint all right. No heat, swelling or pain. Motion perfect, I re-applied the splint and kept it on for a few days, when I permanently removed it. From all I could learn, the dislocation must have occurred before the child

was born. It seemed strange that no soreness or inflammation should have followed so extensive a dislocation. NORMAN GRAY, M.D.

Columbus, Ohio, February, 1st, 1880.

NEWS AND MISCELLANY.

Test for Pepsin.

Dr. Carl L. Jensen, after showing the faults in the usual methods of testing pepsin, gives the following directions for testing its efficiency, claiming that the pepsin he prepares will stand this test: Dissolve thoroughly two grains of pepsin in twenty-four ounces of water (do not use hot water), have the solution well stirred up. To three ounces of this solution (which will contain ¼ grain of pepsin), add fifteen drops of acid muriatic, c. p., and two hundred and fifty grains of boiled albumen, previously pressed through a sieve having thirty threads or meshes to the inch. Perform the test in a six-ounce bottle, placed in a water bath, and maintain a temperature of 100° Fah. for six hours, shaking the bottle every ten minutes. At the end of six hours strain the solution from the undissolved albumen, and place the residue upon several layers of blotting paper, until so much moisture is absorbed that the albumen has regained its former consistence, then weigh it and deduct. Dr. Jensen believes that one grain of his pepsin will dissolve nearly one thousand grains of albumen.

A Worthy Charity.

The Pennsylvania Institution for the Instruction of the Blind have issued a little circular, from which we note that there are nearly four thousand blind persons in this State, nine hundred and sixty-eight of whom are in Philadelphia county alone. The Pennsylvania Institution for the Instruction of the Blind will receive applicants between the ages of ten and twenty-five. The Pennsylvania Working Home for Blind Men will receive those between the ages of twenty-five and fifty, to learn trades and receive employment therein. The Pennsylvania Industrial Home for Blind Women will instruct and employ blind females of twenty-one years and upward. The blind in many counties know nothing about these institutions. It should be the duty of all citizens to avail themselves of these institutions for the relief of the blind of their neighborhood. For further information address William Chapin, Principal of the Pennsylvania Institution for the Instruction of the Blind, Philadelphia, Pa.

An Enterprising Vaccinator.

A pleasant-looking, middle aged man recently made his appearance in the upper part of Hunterdon County, New Jersey. He said that he was a physician sent by the Board of Health of Jersey City to vaccinate the people of the county. His affable manners and apparent air of authority convinced most of his hearers that he told the truth. He stated that the Board had ordered him to charge one dollar for every adult and fifty cents for every child whom he vaccinated, in order to defray the expenses incurred. He reduced the price when the parties were too poor to pay the sum asked, and even vaccinated some for nothing. He went from house to house in a buggy, and returned to the large towns at night. The fact that he was a fraud, and that the Board of Health had never sent out any physician, did not become known until the man had left the county. He collected a large sum of money.

Cinchona Cultivation in Jamaica.

New Remedies quotes from the New York *Times* some remarks on this subject, a few points from which are of interest. Jamaica offers great natural advantages to the cinchona cultivator. At present England takes all the bark grown there at the remunerative price of from eighty cents to two dollars and five cents a pound. Many gentlemen in the island, including the Governor, are engaging in the cultivation of the trees. The business is daily increasing, and the demand on the Botanical Department for seeds and trees can hardly be supplied. The profit to be derived is very great, though the enterprise would require at least $2500 capital. The yield, at a low estimate, would be worth $9000 per acre.

Disagreement among Physicians.

An exchange says that an interesting difference of opinion, that can be settled only by time, now exists between Professor Depaul and Dr. Tillaux, concerning a woman, more than seventy years of age, who has been an ardent worshipper at the shrines of both Venus and Bacchus. The Professor believes her to be pregnant, while the doctor is sure that the abdominal enlargement is due to a tumor of the liver. We will wait and discover the truth.

Personal.

From the *British Medical Journal* we learn that on November 12th several of the chief hospital surgeons of Paris gave a banquet to Mr. Spencer Wells. Professor Gosselin, in a happily improvised speech, rendered homage to the great services which Mr. Spencer Wells has rendered to humanity by demonstrating "the possibility and the opportunism of that splendid operation, ovariotomy." This was a well deserved compliment to a distinguished man.

Styptic Colloid.

The *Chemist and Druggist* (London) says that the following will instantly coagulate blood, forming a consistent clot, under which wounds will readily heal:—

Collodion,	100 parts
Carbolic acid.	10 "
Tannic acid,	5 "
Benzoic acid,	5 "

Mix the ingredients in the above order.

Alumni Association of Albany Medical College.

The annual dinner of the Alumni Association of the Albany Medical College will take place at the Delavan House, Wednesday, March 1st, 1882, immediately after the Commencement exercise at Tweddle Hall.

Obligatory Vaccination in Switzerland.

The Swiss National Council have made vaccination obligatory in Switzerland, by a vote of ninety to twenty-three. Every infant must be vaccinated during the first year of life, or at latest, during the second year. Infants born out of Switzerland, if not previously vaccinated, must submit to the same rule. No child will be allowed to attend either public or private school without a certificate of vaccination.

Ambulance Service in London.

A meeting to consider the feasibility of establishing a general hospital ambulance service was recently held in London. Many influential persons were present, including representatives from the principal hospitals. The Duke of Cambridge presided. Resolutions were passed in favor of the adoption of the New York system.

Diphtheritic Contagium.

We have received the supplement to the *National Board of Health Bulletin*, containing a full report of the investigations into the "Nature of the Diphtheritic Contagium," which have been conducted by Professor Wood and Dr. H. C. Formad. In a subsequent issue we will give a digest of the report.

Purification of Air in Hospitals.

Dr. Neale recommends, in the London *Medical Times and Gazette*, a chemical punkah, the fan of which, being made of vegetable fibre, is saturated with caustic soda solution, fed from a small tank above.

Items.

—Hepatotomy has been recently performed three times, successfully, by Mr. Lawson Tait, of Birmingham, England.

—Fifteen prominent citizens of Minnesota have been affected with trichinæ, from eating raw ham. Three of the number died

—On Boston authority it is stated that the latest high school translation of "*Arma virumque cano*" is "I sing of arms and the virus."

—Dr. C. H. Merrick, Seattle, W. T., will send to any address, on the receipt of a three-cent stamp, "The Decimal System of Writing Prescriptions."

—A Chicago druggist, supposing he was connected with a wholesale house, telephoned to the lady at the exchange, "Have you any large black nipples?" He is still waiting for a reply.

—Reports from all parts of the country indicate that smallpox is on the increase. It is very prevalent in New York, while fresh cases are reported from Massachusetts, Virginia, and Chicago. The disease is under control in this city, and the number of new cases reported is daily diminishing.

—A gentleman entered the office of a medical friend, and taking up what he supposed to be a toothpick from the table, began picking his teeth. Presently he pricked his tongue, and a consequent exclamation called the doctor's attention to what was going on. The supposed toothpick was a vaccine point, and it "took."

OBITUARY NOTICES.

—Dr. George T. Campbell, an old and respected physician of Skaneateles, N. Y., died on the 12th inst.

—Dr. Charles F. Stansbury died suddenly, from heart disease, in Georgetown, D. C., Wednesday, February 1st. Dr. Stansbury was born in New York City, in 1821, and has been prominently connected with the Masonic Order and with journalism, having been at one time a leading writer on the *National Intelligencer*.

—Dr. Isaac H. Conrad, a well known physician of this city, died, February 1st, of Bright's disease, in the 68th year of his age. Dr. Conrad was a descendant of one of the twelve families of German Friends who came from Cusheim, with Daniel Francis Pastorius, in 1683, and were the first settlers in Germantown. He pursued the practice of his profession in Philadelphia, where he spent his entire life, and his services were rendered with equal freedom and ability to all who called on him, regardless of their means.

—Dr. James C. Jackson, for over thirty years a physician in Hartford, Conn., died Feb. 7th, of typhoid pneumonia. Dr. Jackson was born in Cornish, N. H., Aug. 22d, 1818. After a preliminary course of study, he entered Dartmouth College, in the Class of '44, and studied medicine at the same college, and subsequently in Philadelphia, where he received his degree of M. D., in 1847. He has been one of the most respected of the citizens of Hartford, and his death is felt to be a public loss. He was conscious up to within a few moments of his death, and felt his own pulse and noted his condition. He was twice married but had no children.

MARRIAGES.

COMEGYS—NOTSON.—At Columbus Barracks, O., Feb. 14th, by the Rev. C. H. Babcock, Captain Edward Tiffin Comegys, M.D., U. S. A., and Miss Minnie G. Notson.

LITTLE—HETHERINGTON.—On Thursday evening, February 9, 1882, at the residence of the bride, by Rev. C. F. Turner, George Little, M.D., and Miss Jennie Hetherington, both of Philadelphia.

SATTLER—RAY.—In Cincinnati, Ohio, February 9, 1882, Dr. Robert Sattler and Miss Maud Ray.

DEATHS.

MARCY.—At Cape May, N. J., Samuel S. Marcy, M.D., in the 89th year of his age.

MASON.—In New York, on Sunday, Feb. 12, 1882, Theodore L. Mason, M.D., in the 79th year of his age.

VIELE.—Entered into rest on Sunday, Feb. 12th, Augustus Viele, M.D., of New York, in the 67th year of his age.

WHITE.—In Riverton, N. J., on the 12th inst., Robert White, M.D., aged 24 years.

WHITALL.—In New York, on the 18th instant, at his residence, No. 607 Lexington av., Samuel Whitall, M.D., aged 41 years.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

Lecture.

THE DISEASES OF PREGNANCY.

BY JAMES W. M'LANE, M.D.,

Professor of Obstetrics in the College of Physicians and Surgeons, New York.

Albuminuria.

(*Continued from page 7.*)

Gentlemen: We will return this morning to the subject which engaged our attention at the last lecture, the diseases of pregnancy. At the close of the hour we were considering albuminuria of pregnancy, to which I would again direct your attention. We saw that the cause of this disorder could not be due alone to pressure of the gravid uterus. Although there are certain facts which go to show that pressure may have something to do with the production of it. There are certain conditions, as in large fibroid tumors of the uterus, ovarian tumors, etc., in which the interference with the renal circulation from pressure is greater than that in pregnancy, but in which, nevertheless, albuminuria does not exist.

The true explanation of the albuminuria of pregnancy is not that it is due to any one cause, for we find, if we take any one of the alleged causes and try to account for the presence of all cases on that basis alone, that there are instances in which such an explanation is not at all satisfactory. In some cases it is due to one condition, in others to another; but in all cases we find underlying the albuminuria of pregnancy a condition of the blood which certainly predisposes to it. The condition of the mother's blood during pregnancy is all the time, as it were, in a deteriorated state, and this condition is exaggerated in the placenta by the giving up on the part of the fœtus, to the mother's circulation, various impurities. When to this state of the mother's blood the condition of pressure of the gravid uterus is added, you have, in certain cases, the two causes which go to produce albuminuria. Some writers, especially those across the water, claim that many of the cases of pregnancy in which albuminuria is present, but which go on to full term and are delivered successfully, terminate, in a comparatively short period of time, in death from Bright's disease of the kidney. If this were the case I should be much more anxious than I am at present, upon finding albumen in the urine of a pregnant woman; but I do not believe that it holds true, at least in this country. I have had patients who suffered from the albuminuria of pregnancy ten or fifteen years ago bear several children since, and are perfectly well to-day. In one of these cases the attack of albuminuria in the first pregnancy was so severe that I was compelled to resort to venesection three times in order to reduce the congestion of the kidney. Some cases of chronic Bright's disease of the kidney may be supposed to arise in an attack of albuminuria during pregnancy, when, in fact, it dated back a number of years earlier, to an attack of, perhaps, scarlet fever, and was simply aggravated during pregnancy in a manner then to show for the first time symptoms which would attract the attention of the patient or physician. But a simple case of albuminuria of pregnancy, I believe, will pass away under proper treatment. If not properly cared for, it may result in eclampsia and destroy life, but I have never seen a patient die in con-

sequence of remote effects of the albuminuria of pregnancy, say within a year or two after delivery, the symptoms of albuminuria in the meantime having subsided.

The appearance of any amount of albumen in the urine during pregnancy always gives me more or less anxiety, for I cannot tell to what extent it may go. If it appear in large amount and continue for some time, it will almost surely result in convulsions, one of the worst accidents which can befall a pregnant woman. Therefore, whenever a pregnant woman passes urine which contains more or less albumen, she should be kept under observation until after confinement. It is my rule always to examine the urine at stated intervals before confinement; and if a woman refuse to conform to this rule, and let me have a specimen of the urine as often as directed, for examination, I will not attend the case in labor; for, should any unfavorable symptoms develop in the meantime, the physician is the one on whom the blame falls.

Symptoms.—I will again speak of the symptoms associated with albuminuria of pregnancy, one of which is the presence of albumen in the urine. Headache. If this be persistent, and present every morning when the patient wakes, it should never go unheeded, but should lead to an examination of the urine. Œdema. This is especially to be regarded if it occur in the face and upper extremity, not alone in the ankles and feet. Vomiting, especially when it occurs after the first weeks, and is not to be accounted for by other conditions, is a symptom of albuminuria. Then there is a feeling of depression. The patient does not feel certain that she is as well as she would like to be. Then, trouble with vision, seeing motes floating in the air, etc., along with other symptoms just mentioned, as gastric irritability, headache, œdema of the face, a moderate amount of albumen in the urine, indicates a condition which requires pretty active treatment. Now, these symptoms of gastric irritation, of convulsions, etc., have been ascribed to a uræmic condition of the blood, and to the existence of particular poisonous properties in the blood. Now, we can say this, at any rate, that the kidneys, while they are secreting this large amount of albumen from the blood, are not taking away the effete matter which they should, and which, therefore, is allowed to remain in the circulating fluid to produce the disturbances belonging to albuminuria. This frequently causes imperfect development in the fœtus, sometimes leading to abortion, sometimes to a still-born labor, sometimes to an imperfectly developed child. I have seen a good many cases in which the albumen in the urine was moderate in amount, but led to labor at the seventh or eighth month, and to the birth of a small, shriveled, dead child.

The *prognosis* will depend upon the degree of congestion of the kidney, upon the general condition of the patient, and upon the question as to whether she will be properly treated. If let alone, the prognosis is bad; if properly treated, the prognosis is fair. There is always a certain amount of danger connected with these cases, shown by the fact that in twenty per cent., if let alone, you will have convulsive seizures. Now, the convulsive seizure may occur long before time for parturition. The prognosis in one case might be good, while in another it might be unfavorable. You meet with this condition much more frequently in primipara than in multipara, the reason being that, the abdominal walls not yet having been distended by a previous pregnancy, the kidneys are more pressed upon. I have a patient now in whom I examine the urine twice a fortnight, morning and evening. The morning urine did contain twenty-five per cent. of albumen; it now contains ten per cent.; while the evening urine contains only one-half of one per cent. I believe that in this case the presence of an extra amount of albumen in the urine in the morning is due to the recumbent position, causing pressure upon the kidneys during the night. When the patient stands up the uterus falls forward and the renal veins are less pressed upon.

The amount of albumen will sometimes lead us to correctly estimate the prognosis; in others it will not. A small amount of albumen with the presence of nervous symptoms before alluded to shows a case that is far worse than one in which there is a good deal of albumen without any nervous symptoms. You may have a case in which there is fifty per cent. of albumen for a week, and if uræmic symptoms do not develop, you may carry your patient through and deliver her of a healthy child.

Treatment.—You will infer, from what I have said, that the treatment is not by any means the same in all cases. You do not, for instance, always commence by giving cathartics. I will first speak of the treatment of a mild case, then of one more severe, and then of one quite severe.

You may examine the urine of a pregnant woman, say, after the fifth or sixth month, and at your first examination you may find ten per cent. of albumen; at the next, fifteen per cent.; and at still the next, twenty per cent.; there you have a case which is developing pretty rapidly in

this particular symptom, and yet the patient has no nervous symptoms. She may then eat too much food, particularly that of a nitrogenous character, after which she complains of headache on first rising in the morning, the headache, perhaps, disappearing after she has been about the house a while. Still, if this patient passed an ordinary amount of urine, there would be no necessity for treatment which could at all be called heroic. I would first see that she had a regular movement from the bowels every day, and for this purpose I would use some saline that would produce an exosmosis from the vessels in the intestine. The pathological condition, you will remember, is one of congestion of the kidney, with pressure, and our object is to relieve this, and yet not deplete the patient more than is necessary. We can make the intestine and the skin do pretty much all the work necessary to be done by the kidney, but which in its present condition the kidney fails to do. Having, by the saline cathartic, produced a fluid movement every morning, the patient should be put upon milk diet. I mean by milk diet, that the woman have no other food during the twenty four hours. The quantity of milk necessary to keep a person from feeling hungry, and to keep up the nutrition of the body, is somewhere from three to four quarts. Most women will take three quarts of milk without difficulty; four quarts may be a little irksome to take, but if they feel hungry they can easily add to the three quarts a fourth. I generally get them to take this amount by telling them to take a glass every hour during the day, and at mealtime to take about three glasses. Milk, taken in this way, is easily assimilated, and is not likely to cause the patient any digestive inconvenience; but, if necessary, you may add to it some lime water. You know that in many cases of Bright's disease, treated by giving the patient a milk diet, and keeping him in an equable temperature, life has been prolonged a long time. If, by this treatment, the amount of albumen in the urine greatly diminishes, the patient might be allowed to take with the milk some other simple nourishment; but should the amount of albumen again increase in quantity, I would put her back again upon the exclusively milk diet. This simple treatment will answer for some cases. Another point I would add, namely, that if the blood seem to be hydræmic, and there can be heard an anæmic bruit, the patient should be given iron. For this purpose I find the tincture of chloride of iron one of the best preparations of this drug. I have never seen it produce any tendency toward miscarriage, which some claim that it does. It may be administered in ten-drop doses, three times a day, and the patient will often be greatly benefited by it.

Now, suppose a patient, at the sixth or seventh month, takes a ride out in the park, without sufficient flannel clothing, exposing herself to the cold, and at night finds that she passes only a small quantity of urine; in the morning waking up with a severe headache, but without any stomach disturbance. When you are now called to see her, she complains of severe headache, and of dimness of vision, due to headache, and on examining the urine you may find that it contains sixty per cent. of albumen, whereas, three or four days prior, it was perfectly clear. Now, it would not do to treat such a case simply in the way that was mentioned above. The thing to do for that patient is to take away some blood. I do not mean by cupping, but by the lancet. I am aware that bleeding has gone out of fashion, but how many other things have gone out of fashion to be renewed again on proper occasions? and I believe that bleeding will again be resorted to more frequently than it is now. I have bled patients during pregnancy, time after time, and with the best results. I find that in some cases venesection controls the tendency to eclampsia in albuminuria as nothing else will do. There may not be so many people at the present day who would bear bleeding as well as those of many years ago, but when you have a patient, a plethoric woman, with the above-mentioned symptoms, I would advise you to bleed her at once. The result of this venesection is that the headache disappears. In one case in which I bled a patient, when I first saw her she had the kind of headache referred to, and great dimness of vision. The amount of urine passed was quite small, and on boiling it there was absolute solidification, from the presence of albumen. I bled her, and it was the opinion of two physicians who saw her afterward, as well as my own, that had she not been bled she would have died in convulsions within twenty-four hours. There was already slight twitching of the muscles of the eyelid. Sixteen ounces of blood were withdrawn, and the patient then remarked that the headache had disappeared. She was then given ten grains of calomel, which produced a free evacuation from the bowels, and afterward she received a diuretic. The result of this treatment was that she continued to do well for two or three weeks, when the symptoms became such as to require bleeding again, and two or three weeks subsequently she was bled a third time. In a consultation of three physicians it was unanimously decided that

premature labor should be induced. She was also bled a fourth time. Now, I have attended that woman in five pregnancies since, and she is perfectly well to-day.

If, however, the condition of the patient does not make you feel justified in withdrawing blood from the arm, you will find benefit to arise from placing cups, wet or dry ones, over the loins. If the patient be one of those women whose state is always one either of perfect bliss or excruciating torture, you may apply dry cups. As soon as you put them on the patient will tell you that they cause her intense agony, and that they must be removed; but expecting this beforehand, you will be talking about something else, and thus divert her thoughts until sufficient time has slipped away to produce decided benefit by this method of counter-irritation. In the meantime you will have sent a couple of pounds of flaxseed meal to the kitchen to be prepared as a poultice, which you will place between two layers of linen cloth and apply to the parts yourself, or have somebody to do it to whom you have given explicit instructions. When you want a warm poultice applied, if you do not give explicit directions as to how it shall be made and put on, it will probably be done as most people do it, made and applied as thin as a buckwheat cake. A poultice of that description cannot retain heat and moisture any length of time. It must be made an inch or an inch and a half thick, and large enough to cover the patient's back at the loins. A bandage should then be applied, as in parturition, and the patient should lie abed. Then, after giving her some cathartic, either calomel or a saline, administer some diuretic, and a very good one is the citrate of potassa, say ten grains every three or four hours, together with an infusion of digitalis, which of itself is a diuretic, but a much more efficient one when mixed with the citrate. The patient will probably be thirsty, and a good drink is one of the mineral waters, say the Apollinaris, the Vichy, or the Seltzer. A small quantity of bitartrate of potassa added to a good deal of water, and flavored with a little of the oil of lemon, makes a very good artificial drink, which acts as a diuretic.

By these means you can sometimes diminish the quantity of albumen in the urine, from fifty per cent. to five per cent. within twenty-four hours, and get your patient absolutely out of danger for the time being. I would then place her upon a milk diet, and have her live in a tolerably quiet way. And a word with regard to living in a quiet way. I have noticed over and over again that patients with albuminuria in pregnancy, especially those of nervous susceptibility, do well enough as long as they live up to the rules you prescribe for them, but the moment they go beyond them the quantity of albumen again increases. They will go, for example, to a dinner party, or to the theatre, or opera, where the atmosphere is unfit to breathe, being loaded with carbonic acid. Then visit one of the fashionable resorts and have a late supper. The next morning you will, perhaps, find fifty per cent. of albumen in the urine.

Taking an unusual amount of exercise, but an amount which would not fatigue a healthy adult, will increase the quantity of albumen in the urine of these patients. Now, you wish your patient to get the benefit of fresh air, and yet she must avoid too much exercise, and you are, therefore, at a loss to know what is best—to recommend her to go out in the open air, or to remain at home. Of this, however, I am certain, that in order to get fresh air, the patient should sleep in a room in which the window is left wide open, and as a protective against cold she should sleep in flannel clothing. Now, I am sure you can have no conception of the difficulty you will have in getting a woman to sleep in flannel. But it is very necessary that she should do so. I do not know why it is that women have such an aversion to flannel. Some will say they would rather die of albuminuria than wear flannel. It is probably because it irritates the skin, but I believe that that fact does good. When I say flannel, I do not mean one of those sham substitutes for it which have been invented during modern days. I mean the flannel made of pure wool. You can easily understand that while the kidney is in this condition the balance of function between the kidney and skin should be carefully guarded, lest, upon disturbing the function of the skin, the amount of effete matter circulating in the blood be increased and the patient be thrown into convulsions. I have known patients to die in whom the amount of albumen in the urine previous to undue exposure of the skin showed that by proper care in the way of dress they might be alive to-day.

The skin, then, should be kept warm. The food should be of a nature that will not irritate the kidney, and such as will flush or wash it out. Milk will fulfill these requirements. If the blood be poor, thin, and bad, give the tincture of chloride of iron. If it be possible for the patient to exercise without increasing the amount of albumen in the urine, have her do so. If walking increases the amount of albumen try riding, or if

riding is first tried and produces an increase in the quantity of albumen, then try walking. The question whether the albumen is increased by exercise can only be determined by examination of the urine, perhaps frequently repeated. Then, if the amount of albumen runs up to thirty, forty, or fifty per cent., as the time of viability is reached, I would most strongly advise you to terminate pregnancy, and you will never regret having done so. I believe, however, that with this increase in the amount of albumen, and growing bad symptoms, if you do not terminate pregnancy at this time you will often have occasion to regret it. You can induce labor at the eighth month with comparative safety. Now, what change is going to take place during the last thirty days of pregnancy? The child, which now perhaps weighs three pounds and a half, is going to increase in weight up to seven pounds, and if at the present time the pressure upon the kidneys and the condition of the blood is such as to cause this large amount of albumen in the urine, what will be the state of things when this rapid growth of the child occurs? Convulsions may occur at any time, resulting, perhaps, in death both to mother and child.

Finally, you should place the woman in such relations that she may avoid, as far as possible, the dangers of the albuminuria of pregnancy. As said before, she should be placed in quiet surroundings, advised to sleep plenty, to avoid theatres, churches, and other places where a number of persons are congregated together to vitiate the atmosphere. She should avoid late suppers and overheating at any time; she should eat only easily digested food; she should avoid excitement and exposure to cold. In telling her the necessity for observing these general rules you should not excite in the mind of the pregnant woman undue apprehension, but at the same time she should understand that if she disobeys your instructions you will not be answerable for the results; that if she follows your advice everything will probably come out all right.

Communications.

ABSCESSES OF THE ABDOMINAL CAVITY.

Paper read before the Dearborn (Indiana) County Medical Society,

BY JOHN ELFERS, M.D.

Abscesses of this cavity, though not of frequent occurrence, yet are common enough to demand the careful study of every practitioner of medicine. When we consider their gradual and insidious mode of development, their great similarity to other diseases, it is not a matter of surprise that the most eminent practitioners and accurate observers have never suspected them at different times until discovered post-mortem.

And no doubt, if in some of the fatal cases of so-called typho-malarial fevers post-mortem examinations were made, it would be found that they were really cases of septicæmia, caused by collections of pus in some of the abdominal organs. An abscess of the liver may form and a portion of the organ become converted into a pus cavity, without any symptoms pointing to that organ.

Many cases follow attacks of dysentery, in others, malarial poisoning is the cause. Calculi and traumatic injuries, and lastly, emboli, may be followed by abscess. The embolus being carried into the liver by the portal circulation, it finally reaches a vessel so small as to arrest its further progress. The symptoms are a sense of weight in the right hypochondriac region; general malaise, attended by fever; coated tongue; bowels generally constipated; urine scant and high colored. If the inflammatory process is near enough to the surface to involve the peritoneum, there may be severe pain, but if this membrane is not involved, there may be no pain at all. Sometimes there is pain in the right scapular region, but this may be caused by disorders of the stomach, as well as the liver. In some cases nausea and vomiting are prominent symptoms. Sometimes there is marked soreness and a sensation of stiffness in the right leg, owing to encroachment of the disease on the psoas muscles and nerves in that locality. This was very marked in a case which came under my observation. Some authors claim that there is no elevation of temperature until after the pus is formed, and that then the fever is the result of septicæmia. In cases where the pus is working its way to the surface, there is generally considerable swelling, and in some cases this is very great. Jaundice is present in about one-third of the cases. This is most marked where there are calculi, or where there is considerable swelling of the mucous membrane of the ductus communis choledochus, thereby preventing the passage of bile into the duodenum, and necessitating its reabsorption into the blood.

I will now briefly give the clinical history of a case which came under my observation. Was called, February 5th, 1880, to see Caroline L., aged thirty-three, married, mother of four children, the youngest five months old. Has enjoyed fair health during the last year, until about one

week previous to my first visit. During this time she has complained of pain in the right side; headache; fever; anorexia; bowels constipated; urine scant and high colored, and stiffness and pain in the right leg.

Present Condition.—A woman of medium size, fairly nourished and dark complexion; heart and lungs apparently normal; firm pressure over the right side causes some pain, and over the centre of the tenth rib is a very sensitive spot about the size of a silver dollar—this was the only sensitive point that could be found; no swelling appreciable; pulse 100; temperature 102° Fahr.; tongue coated with a heavy yellow coat; bowels constipated; the quantity of urine diminished and high colored and well marked jaundice. The secretion of the mammary glands is nearly arrested, so that the child has to be fed, and is not put to the breast at all. Prescribed cathartics and diuretics, to be followed by cinchonidia and ipecac; ordered mustard plaster to be applied to the right side.

Feb. 6th. Somewhat better; has had several fecal evacuations; also free secretion of urine; pulse not so frequent; temperature 101°; considerable soreness of right side, but no swelling; still complains of stiffness of right leg.

Feb. 7th. No change; continued treatment. From this date until the 13th of February there was but little change in the symptoms; fever continued; sometimes morning, at other times evening exacerbations, each exacerbation being followed by or terminating in a profuse sweat. The bowels never moved without laxatives, and it was necessary to prescribe diuretics to stimulate the kidneys to perform their function. The tender spot in the right side had, in the meantime, changed its position, until now it occupied a position half way between the twelfth rib and the crest of the ilium, and two or three inches anterior to the transverse processes of the lumbar vertebræ.

Feb. 13th. Much better; temperature nearly normal; appetite improving, and the secretion of milk has returned, so that now she can nourish her child. There is some soreness in the right side, but it is supposed to be due to the blistering, which had been resorted to several times.

Feb. 14th. But little change.

Feb. 15th. Not so well; complains much of her side; her tongue is getting dry and red; abdomen is becoming tympanitic; bowels constipated; voids no urine; there is some swelling of her right side; does not sleep any during the night.

Feb. 16th. Symptoms same as yesterday.

Feb. 17th. Has been very restless all night; there is considerable swelling of the right side; no movement of bowels nor action of kidneys.

Dr. Barkley, of Farmers' Retreat, was now called in consultation; arrived at 5 P.M., when her temperature was 104°; pulse 140; other symptoms same as this morning. Prescribed a febrifuge for the high fever, to be followed by a mercurial purge, giving 10 grains of calomel for the first dose and three doses of 3 grains each afterward, to be given three hours apart. Applied blister and flaxseed poultice to the tumor, giving morphia to relieve pain.

Feb. 18th. Not much better; there has been no movement of the bowels after taking all the calomel, and has voided no urine; temperature not so high; does not suffer so much pain, but this is owing to the morphia; she has considerable tympanites; ordered some castor oil; continued the other treatment.

Feb. 19th. No change. After Dr. Barkley's arrival an enema was given, after which she had a free evacuation of the bowels, at the same time voiding urine. After the bowels had moved the tympanites disappeared. Does not suffer much pain. Continued the treatment, and in addition gave fld. ext. cascara sagrada, in ʒ doses, but without receiving the desired effect.

February 20th. Little better. Temperature 102, pulse 108. Continued treatment.

February 21st. We saw her at 10 A.M. As our laxatives and diuretics had failed we again resorted to an enema, with good effect. There is considerable tympanites; tongue is dry and red; has been sweating profusely during the night. Temperature 102°, pulse 100. From this time until 26th there was very little change. She had constant elevation of temperature, attended by night sweats; no appetite, with a typhoid condition of the system. The pain in her side would be very severe at times, then at intervals would be absent.

February 25th. We noticed considerable enlargement of the tumor.

February 26th. The enlargement is more marked and deep; fluctuation can be detected. An exploring needle was passed into the tumor about three-fourths of an inch, but without finding any pus. Thinking that further interference was not justifiable we continued the local applications and other treatment, giving as much beef essence and egg-nog as we could induce our patient to take, to sustain her until the pus would be near enough to the surface to be evacuated.

February 27th. No better.

February 28th. Rather failing. Abscess enlarging very rapidly and causing much pain.

February 29th. Has had severe pain in the right side during the night, and is much prostrated. Temperature 102°, pulse 120. On palpating the tumor, deep fluctuation can be detected. After using an ether spray Dr. Barkley made another exploration, and a drop of pus followed the instrument. A free incision was made immediately, when about a pint of laudable pus was discharged, with immediate improvement in the condition of our patient.

March 1st. Much better. Temperature 101°, pulse 108. Has had some pain during the night, but it is supposed to be due to the collection of pus in the cavity, the incision having closed during the night. After reopening the wound a large quantity of pus was again discharged, relieving her very materially. A tent was now introduced, keeping the wound open, thereby preventing the further accumulation of pus.

March 2d. Temperature 98½, pulse 96; is improving. The abscess continued discharging until March 10th, when it ceased; discharging altogether between thirty-five and forty ounces of pus. After the pus was evacuated the temperature never exceeded 99°; pulse ranged from 84 to 96; night sweats ceased; tympanites disappeared; appetite returned, and our patient made a rapid recovery, considering the critical condition she was in but a short time before. The most annoying sequel she complained of was the stiffness of her right leg and a sensation as if it was shorter than the other one, which continued for some time after she was around and attending to her ordinary duties, but finally disappeared altogether. The diagnosis in this case was not clear in the beginning; the only symptom pointing to the liver being the seat of the trouble was the jaundice. It is true there was considerable pain in the epigastric and right hypochondriac region, but that is nearly always present in ordinary remitting fever, of which we had the characteristic symptoms the first two weeks of the disease; but that it was not a malarial or continued fever is proven by the fact that the fever ceased immediately after the pus was evacuated. Doubtless the pus was formed during the first two weeks, and that subsequently the fever was due to septicæmia while the pus was making its way to the surface. The prognosis in these cases should always be guarded. If the abscess opens into the lungs, externally through the skin, or into the intestines, many cases recover; but if it opens into the peritoneal cavity the termination is almost invariably fatal. By the early use of the aspirator many cases may recover that would otherwise prove fatal.

The treatment in these cases should be, first, to limit the inflammatory action; second, palliative; third, to remove the pus at the earliest moment practicable. The first indication may be met by giving large doses of quinia, it being claimed that it has the power to stop the migration of white corpuscles; then to relieve the portal congestion cathartics should be given; those producing the greatest serous transudation with the least irritation possible are the most desirable. The saline purgatives, of which the sulphate of magnesia is generally at hand and very effectual, should be given during the active or inflammatory stage; where this is inadmissible, calomel may be given. All cathartics which have a cholagogue effect should be avoided; of this class aloes, podophyllin, rhei, colocynth, jalap, hold a foremost rank; but this objection cannot be made to calomel, as recent experiments seem to prove that it not only has no power to increase the flow of bile, but that the quantity is actually diminished during its administration. To relieve pain, anodynes must be given freely. Morphia given in small doses and frequently repeated until relief is obtained, is perhaps the best way where the patient is not near enough to the physician's office to afford an opportunity for frequent visits; but where they are near enough to be seen often, giving ordinary doses hypodermically is perhaps the best and most satisfactory. Local applications should be kept up constantly, in the form of poultices and blisters, thereby relieving tension and inviting the pus to the surface. We are taught by some text-books to use the aspirator early, to remove the pus, if any is present, and if not, the puncture will do no harm, but on the contrary, that frequent punctures with the aspirator needle are beneficial. When the tumor points externally we should be careful to satisfy ourselves that there are firm adhesions between the tumor and abdominal walls, then make a free incision, keep a tent in the opening, establish thorough drainage; and where the discharge is offensive and unhealthy, injections of weak solutions of carbolic acid will be beneficial. If, however, the pus is laudable, without any offensive odor, a free outlet is all that is necessary. In addition, keep up our patient's strength with good food and tonics, treating other symptoms as they arise.

Perinephritic Abscess.

By perinephritic abscess is meant inflammation, followed by suppuration of the connective tissue around the kidney. The most frequent causes are contusions, or any traumatic injuries. Some authors claim that a strain may be the

cause. In puerperal cases it may follow pelvic cellulitis, the inflammation extending up to the kidney. Symptoms are the same as in abscesses of other regions; there is generally deep-seated pain, aggravated by pressure; swelling, with discoloration of the skin, though the discoloration may be absent in some cases. It often occurs in persons of broken-down constitutions. Prognosis should be guarded. In subjects previously healthy, where the pus is evacuated externally, recovery is the rule. On the contrary, where the pus burrows into the surrounding structures, and in broken-down subjects, the prognosis is grave. Treatment in robust subjects should be antiphlogistic. The bowels should be thoroughly evacuated. If there is much disturbance of the circulation, arterial sedatives, with anodynes to relieve pain, are indicated. Emollient poultices, with a blister occasionally, are the best local applications. The pus should be evacuated as soon as possible, to prevent its burrowing in the surrounding structures. Purulent collections in the connective tissue around the cæcum are more common than that of the kidney.

Among the causes are external injuries, foreign bodies in the bowel, or the inflammation of ordinary typhlitis extending into the connective tissue. Symptoms are, a sense of weight in the right iliac and lumbar regions, swelling and pain, the pain frequently extending down the thigh. The thigh is flexed upon the abdomen, to relax the psoas muscles and structures of the anterior abdominal wall. The bowels may be constipated, but if there is no typhlitis present there will not necessarily be any interference with the function of the bowel. Sometimes there is nausea and vomiting, with considerable elevation of temperature. In some cases there is considerable depression of the vital powers.

In making our diagnosis we should be careful to distinguish between fecal collections and abscess, since the treatment is quite different. In abscess there is the swelling, severe pain, and constitutional symptoms of abscess. In fecal impaction there is generally no elevation of temperature; there is generally no discoloration of the skin. The collection may resemble a large tumor, be sensitive to pressure, like an abscess, but on making firm pressure some indentation can be made into the fecal mass; but we get no such results in abscess.

The prognosis should be guarded; if the pus evacuates externally the prospect for recovery is fair, but if it opens into the peritoneal cavity the termination is fatal.

Treatment.—Rest, anodynes, given freely, to relieve suffering, and local applications, constitute the treatment in the first stage. If there is no typhlitis a saline cathartic should be given, to evacuate the bowels, but if there is any inflammation of the mucous membrane of the intestine, all purgatives should be avoided. If the constipation is very obstinate, enemas will be beneficial. To remove the pus the aspirator may be used, but it is most desirable to get the pus near the surface; after firm adhesions have formed between the tumor and the abdominal wall, a free incision should be made, to afford a free outlet to the pus and any foreign bodies that may be present. They sometimes are the cause of the suppuration. After an incision is made it should be kept open, to afford free drainage. Then give tonics and plenty of good food, to husband the patient's strength until the danger is past.

THE HYPODERMIC ADMINISTRATION OF CARBOLIC ACID, FOR THE CURE AND REMOVAL OF FOUL AND ILL-CONDITIONED ULCERS, BOTH INTERNALLY AND EXTERNALLY SITUATED, POISONOUS BITES, HÆMORRHOIDS, CARBUNCLES AND TUMORS.

Read before the Texas Medical Association, at its session in the City of Waco, Texas,

BY N. B. KENNEDY, M.D.,

Of Hillsboro, Texas.

Mr. President and Gentlemen—I wish to offer for your consideration, on this occasion, some of the conclusions I have arrived at, during a period of three years, in the administration, hypodermically, of carbolic acid, for the cure and removal of ulcers, poisonous bites, carbuncles and tumors.

Carbolic acid, as you all know, is a solid, obtained from the products of the distillation of coal tar, between a temperature of 300 and 400 degrees. It was discovered by Runge, in 1834, who gave it the name of carboiic acid; but to Dr. Calvert is due the credit of introducing it into general use in the United States and England.

Carbolic acid may be defined to be an antiseptic anæsthetic, with slight caustic properties, and one of the most powerful disinfectants known. It has a very feeble claim to be recognized as an acid, being more closely allied to alcohol than acids, and, in consequence, is sometimes called phenylic alcohol. Carbolic acid has the power of preventing putrefaction in animal substances, arrests fermentation, and coagulates albumen. Carbolic acid in the liquid form is very slightly irritant; and when applied undiluted to the

skin, causes it to turn white, but produces very little pain. In contact with mucous surfaces, it acts in the same manner.

When I commenced, three years ago, experimenting with carbolic acid, hypodermically, it was with a firm belief that I would succeed. The experiments then commenced have ceased to be experiments, but have become established facts. I beg your indulgence while I rehearse to you, in as concise a manner as possible, some of the few out of many successful cases treated hypodermically and locally with carbolic acid.

Case 1.—Mrs. McC., a delicate little woman, I found suffering with hæmorrhoids, nearly as large as a goose egg. I injected, hypodermically, five or six drops of Calvert's undiluted carbolic acid into the centre of the tumor. The pain was but momentary, the anæsthetic effects of the acid following immediately on withdrawal of the needle. Four more injections effected a complete cure in this case.

Case 2.—I was called, August 19th, 1878, to see J. R. D., one of our most esteemed citizens, suffering with fifteen large carbuncles on his back and neck. He was suffering fearful agony, his family informing me he had not slept five minutes in five days and nights. I at once injected four or five drops of carbolic acid into each of the carbuncles with the happiest effects. In five minutes the old gentleman was in a sound and refreshing sleep, which continued without intermission from 4 o'clock P.M. until 9 o'clock A.M. He awoke from sleep greatly refreshed and without pain, and never did have any more pain. Twelve of the carbuncles aborted and three went on to suppuration, or rather, had commenced to suppurate, when I first saw them. A complete cure followed in three weeks.

Case 3.—Was called in the evening to see a boy, ten years old, who had been bitten in the morning by a mountain rattlesnake, in the *dorsum* of the foot. On arrival I found the little fellow suffering terribly, with the foot and leg livid and much swollen. I immediately injected five or six drops of the acid, as near into the bite as I could. The relief from pain was so immediate that the little fellow asked me to let him see the "little thing" that stopped his pain so quick. The swelling rapidly disappeared, and he never suffered another moment's pain.

Case 4.—J.L.F., a well-to do farmer, consulted me about a tumor on the back of his neck, which had commenced to grow and was paining him. I found a fibro-cellular tumor about the size of a small egg, and injected about twenty drops of undiluted acid into the centre of the tumor, which in this case suppurated, but in a week or ten days had entirely disappeared, and left no cicatrix behind.

Case 5.—My friend, Dr. Carmichael, of Peoria, Hill Co., Texas, invited me to see Miss J. A., a young lady, eighteen years old, in the full bloom of womanhood and beauty, for my opinion in reference to a very large tumor in her right breast. Her history was good; she had been in good health all her life. Two years since the *catamenia* was established, synchronous with which she noticed a swelling in the right breast. It had been growing for two years, and was now as large as a child's head. She had never suffered any pain in the gland. I diagnosed it to be a multilocular adenoid tumor. I injected about twenty drops of pure, undiluted acid into the most prominent portion of the tumor. The pain was very slight, the anæsthetic effects following immediately the withdrawal of the needle. I used the remedy once a week, from week to week, for two months, at the expiration of which time the tumor had decreased in size from that of a child's head to that of a goose's egg. I now commenced to use the remedy twice a week, and at this writing the tumor is about as large as a hen's egg, and the indications are favorable for its entire eradication. (Note.—In a month after this paper was read the tumor had entirely disappeared.)

I also use carbolic acid locally with the happiest effects. I was called to see the Rev. Mr. B's wife, who had been confined to her room and bed for two years, and had had various treatments, both from regular and irregular physicians, with but little benefit. An examination, per vaginam, revealed a a fully ulcerated os and cervix uteri, with an exceedingly offensive discharge and smell from the genitalia. I applied a fifty per cent. solution of the acid to the ulcers three times per week, and directed for her a good alterative tonic; and in three months she was the very picture of health.

A highly nervous young lady came to my residence to have a felon lanced, and was clamorous for chloroform, as she feared the pain would kill her. I bathed her finger in pure, undiluted acid, and lanced the felon almost without pain, much to her astonishment.

In conclusion, then, allow me to advance the opinion that in carbolic acid we have one of the most powerful remedies for good in the whole pharmacopœia, and one at no distant day destined to supersede almost all other medical and surgical procedure. An antiseptic and anæsthetic disinfectant, *facile princeps*, in surgical cases.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

A CLINICAL LECTURE BY WILLIAM GOODELL, M. D.,

Professor of Clinical Gynæcology, in the University of Pennsylvania.

Reported by Wm. H. Morrison, M.D.

Carcinoma of the Neck of the Womb—Removal by Scraping. Remarks upon the Use of the Hot Wire in Removing the Neck of the Womb.

Gentlemen:—I am going to bring before you to-day a case of carcinoma of the neck of the womb; but as the woman is not fully etherized, I will talk until she is ready. What have we in that bowl? It is a hæmostatic. One of the best that you can have, because it is found in every house. It is good vinegar. In operations around the womb it is very useful. I do not know that I should care to use vinegar in a case where I wanted union by the first intention; but where you have bleeding and wish to check it, you should use vinegar. If you inject Monsel's solution into the vagina, its astringency is so great that it contracts the vagina to such an extent that you find great difficulty in your further operations. Suppose you have a hemorrhage from the vagina; you put in a sponge soaked in Monsel's solution, but the bleeding continues. You have to remove the sponge, and you are going to have a hard time to get others in, and unless the woman is under ether, she is not going to permit any examination.

This patient is thirty years old, married, and has had several children. I want to impress one thing on your minds; it is this; that carcinoma of the neck of the womb almost never occurs in a sterile woman. I want you to bear that in mind. Remember, in your diagnosis, that carcinoma of the neck of the womb is exceedingly rare in unmarried women, or rather in women who have never borne children. The inference, therefore, is, that carcinoma of the neck of the womb always occurs at the seat of a laceration of the cervix. On the other hand, when you come to cancer of the body of the womb, sarcoma, spindle and round-celled, cylindrical epithelioma, if you choose, these, which are very rare, usually occur in old maids and married women who have never borne children. I propose to-day to remove this cancer. They sometimes bleed furiously; but if the work is done rapidly it is not so alarming,

I want to call your attention to this woman's complexion. We have here the typical leaden color which is supposed to be pathognomonic of cancer. It is very marked in this case. It is an ashy color. After the operation that will disappear. This color is, I think, due to a sort of slow septicæmia. I do not consider it due to poisoning of the blood from the cancerous debris as such. You must not, however, be misled by the color, for sometimes women with advanced cancerous disease will have a fine, blooming complexion. This is especially true when they retain a fair amount of fat.

I shall now begin and rapidly break up these granulations with my finger. This woman does not know what is the matter, and I have been very careful not to tell her. She asked me the question, "Doctor, after this operation will I be well? Will I ever have to have another operation?" I evaded the question, and said, "I am not a prophet, and cannot possibly tell whether you will need another operation." I cannot bear to say *cancer* to these women, and I would advise you not to do it. The husband of a lady has been to see me twice, to make an appointment for bringing his wife from a distance. She has failed to come each time, because she is afraid that I shall tell her that she has a cancer. I have had women, on a number of occasions, say to me, "Now, Doctor, if I have a cancer, don't tell me." It is quite common for women, when the change of life begins, if they have any pelvic pain or trouble, to imagine that they are going to have a cancer.

The whole anterior neck of this womb is gone, and I have to be very careful not to get into the bladder. I shall now use this instrument. It is a gouge forceps, devised by Dr. Remey, of Cincinnati; the object is to have as little hemorrhage as possible; it is a very good instrument. The points which bleed are right in the cancerous mass, but after this has been removed the bleeding becomes less, and then it comes from the edges of the cervix, where the mucous membrane runs on the outside of the neck. In order to control this hemorrhage I employ pressure forceps, when necessary.

This operation is an exceedingly successful one, as a make-shift. This woman has been losing a great deal of blood; she has had considerable pain, but not the agonizing pain that she will have in the course of a year. In cancer of the neck of the womb pain does not exist to any great extent, unless the disease has passed the internal os. You know, gentlemen, that you can insert tenacula and make applications to the cervix, and elicit very little response, but when the sound gets past the internal os, you then cause pain wherever you impinge. This absence of pain often misleads physicians. I have on several occasions diagnosed cases of carcinoma which the physicians had not so considered because there was no pain. When the disease passes the internal os the sufferings are terrible. There is nothing which equals the suffering of a woman lingering on with the disease involving the uterine cavity. I once knew a woman take by the mouth thirty-five grains of morphine in twenty-four hours, before she obtained any relief.

I have now removed every portion of the cervix, and have a funnel-shaped opening leading up to the internal os. As I have said, the results of this operation are very good. The woman's life will be prolonged. Some patients will die from exhaustion; one patient died from the disease involving the stomach; and others die from involvement of the pelvic organs. I say to these women, "I can promise to do you great good. I have cured some cases of this kind. I feel that I can positively promise you that the operation will stop the bleeding and pain for a long time." Sometimes a woman will say, "Now, Doctor, is this a cancer?" I never reply to that straight up and down. I say some-

thing like this, "You have asked me whether this is a cancer. There are varieties of cancer. If you mean is it a hard cancer, like that which comes in the breast, it is not. It belongs to the cancerous class. It is an epithelioma, of the most curable variety." I often use this word epithelioma, and cover my retreat by the use of a long word. Members of the family often say to me, "Do not tell the patient that she has a cancer, for if you do, she will go right down hill." I have known such cases. As soon as the disease was pronounced a cancer, the woman gave up, passed into a state of melancholy, and soon died.

I am now working up toward the bladder. This cancer will some day open into the bladder, but I do not wish to make the opening. Observe the nature of the blood which flows from the vagina. It is watery, because she has lost so much. That is hydræmia. I shall inject some vinegar, to check the oozing. This is not as powerful a hæmostatic as Monsel's solution, but it is much nicer. It is one that you may use with safety. You see that it blackens the blood, as nitric acid does.

The whole anterior part of the neck is not only gone, but I am directly upon the wall of the bladder, and the connective tissues lying below it. There is a space about the size of a silver dollar, where the womb is entirely gone. I am, therefore, a little cautious in what I do in that direction.

You may say to me, "Here is an operation which does not cure, but is simply going to prolong life; it is dangerous?" It looks like a dangerous operation. I have performed the operation a great many times. I kept the account of about fifty cases. I then stopped tabulating, as the history was always the same; a slight rise of temperature in the evening after the operation and the next day, and then no further trouble. I have never lost a patient from this operation—yes, there was one patient who died from tetanus, but she died so long after the operation that we were not sure that the operation had anything to do with it. I always felt that the tetanus was not due to the operation, but to the disease itself. No inflammation has followed the operation, although in two cases, I opened the peritoneum.

I am now working at the posterior surface, and I am a little afraid of getting into the rectum, for the disease has advanced beyond the vaginal junction.

I shall now apply the cautery (Paque'in's). In a former case I applied this cautery and the patient got perfectly well, or rather it all healed excepting a spot about the size of a ten-cent piece. On a future day I applied nitric acid without doing any good. I then concluded to apply the hot iron, without saying anything to her about it. I did so, but she never winced, although she wondered where the smell of burnt flesh came from, and thought that something must have burned in the kitchen. You can in almost all cases (there are some exceptions, to which I shall allude) pass the hot iron into the cervix without giving as much pain as by the application of nitrate of silver; but, on the other hand, just as we have painful hair (I remember seeing, in my young days, a case of plica polonica), as we have cartilage sensitive, which is usually not so, so we do occasionally meet with a case of sensitive cervix.

You observe that I remove the cautery from the vagina every few minutes. I do that for two reasons. First, because it makes so much smoke inside that I cannot see; and, secondly, because it would heat the speculum and burn the woman if I did not.

As regards secondary hemorrhage. Here is an operation where the hemorrhage at the time is sometimes very alarming; do you ever have secondary hemorrhage? I have never seen it. About ten days ago I operated, and there was one point high up where I could not stop the bleeding. The pressure forceps could not be applied; burning did not stop it. I then applied Monsel's solution and partly tamponed the vagina. She lost about a teacupful of blood after that. I have never had hemorrhage coming on some time after the operation when I operated in this way.

Let me say one word about taking off the neck of the womb. Your books tell you to take off the neck of the womb with the hot wire, in preference to the cold wire. but I have given up the hot wire, for I have had secondary hemorrhage of the most frightful character after its use. Some three or four years ago I made a big blunder. A midwife came to me with a prolapse of the womb and vagina. She was very anxious to have the operation performed; she said that she was only sixty years old. I permitted myself to be deluded. I removed the neck of the womb with the hot wire. On the seventeenth day after the operation she had an exceedingly dangerous secondary hemorrhage. I was sent for, and when I arrived I found that the physician had arrested the hemorrhage by a tampon. I removed everything and again tamponed. On the twenty-first day another hemorrhage occurred, and she died before it could be arrested. After her death the superintendent sent for her friends, and they told us that she had come to the hospital without their knowledge, and that she was eighty years old. There is where I made the mistake; in taking her statement, when she looked much older. All the arteries were found in a state of atheromatous degeneration.

About three years ago, I had the wife of a Southern Senator in the hospital. She had carcinoma of the neck of the womb, and I removed it with the hot wire. On the third day a most frightful hemorrhage took place. They sent for me in a hurry, but the lady would have died, if it had not been for the coolness of Dr. Harte, who stopped it with the red hot iron, and plugged the vagina. I stayed in the house for three nights, and the greater part of three days, but the bleeding did not recur. She died some time afterward, from the original trouble.

I assisted a gentleman in this city in an operation with the hot wire. On the fifth day hemorrhage occurred, and we tamponed her *secundum artem.* Several days afterward bleeding again occurred, and the woman died before we could get to the house. Look out for trouble if you use the red hot wire. As I say, all the text-books recommend its use, but it is so dangerous that I do not advise it.

I do not like to tampon the vagina after this operation, for it keeps all the discharges in the vagina, but if I performed this operation at a private house, I should dip a sponge in vinegar, pass it into this cavity and leave it there for forty-eight hours, because the sponge has meshes and into these meshes will dip the inequalities of the cervix. The cervix is going to contract, and every inequality of the cervix is going to find a corresponding depression in the sponge. If I remove the sponge in the twenty-four hours I am going to tear away some of the surface, and may get hemorrhage. I, therefore, leave it until pus has formed. Suppuration begins in twenty-four hours, and in forty-eight hours has advanced sufficiently to allow the removal of the sponge. If at the expiration of this time I find, when I catch the string fastened to the sponge, that it is not going to come away with ease, I leave it for twelve hours longer. The danger from septicæmia is not very great, for the whole surface has been seared with the hot iron, all the blood vessels and lymphatics have been sealed, and a clot has formed in their mouths.

She will begin to smell very badly after forty-eight hours; the vagina will be syringed several times a day with a carbolic acid solution. After the sponge has been removed, it will be syringed at least twice a day. I shall give her a suppository of one grain of opium when she is taken to the ward. The pain of which she will complain will be due to the pressure of the speculum on the coccyx. I always begin to give quinine after the operation. I try to cinchonize the patient within twenty-four hours, so that she will have buzzing in the ears. I give quinine because, in the first place, it is an antipyretic; secondly, it contracts the womb, so that the area of absorption is diminished; and, thirdly, it is an antiseptic.

These cases are to be undertaken without any delay. Just as soon as you have diagnosed a carcinoma propose the operation.

One word in regard to the diagnosis. I do not think that any student who leaves this University will, when he lays his finger on a carcinoma, ever mistake it for anything else; but he may, perhaps, put his finger on a polypus, or a fibroid tumor projecting from the os, or on a bad laceration, and think that he has a cancer. I thought that it was impossible to blunder about a carcinoma; but last summer I had a bad case of laceration of the cervix, which the woman said was done when a child only five months old was born. The tissues were so everted and there were such friable granulations, that I could not at first decide whether or not it was cancerous. I examined the woman closely, and determined that cancer had not occurred. I then proceeded with the operation, which resulted in a perfect cure.

One diagnostic point is that cancer always has friable vegetations and if it is an excavating cancer (usually they are excavating) you can feel a sharp edge around this cavity filled with friable vegetations. I compare it to the crater of a volcano. When the carcinoma projects into the vagina, you distinguish it from polypus and fibroid tumor by finding that in the latter conditions the tumor projects through the mouth of the womb, and you are able to distinguish the neck of the womb, but in the former, the cancer forms a part of the neck of the womb, and cannot be separated from it.

Rheumatic Fever—Death from Pyæmia.

The following interesting case is reported in the London *Medical Times and Gazette*, by Dr. Cockle:—

Ten years ago the patient got wet through, was laid up eight weeks in bed, with severe pains in his knees and shoulders, which pains changed their position to the wrists and ankles later on. The most acute pain was in the left side of the chest; worse on taking a deep breath or coughing. Has never been strong or well since, often having pains in joints; but what troubled him most was the shortness of breath and palpitation on taking any exercise.

On admission the patient complained of pain in the præcordial region; slight pain also in the left knee and ankle, which are a little swollen. Temperature at 6 P. M. 102.6°; pulse 120; respirations 30. Profuse acid perspiration. Heart's action tumultuous; no friction sound or increase in the præcordial dullness. The first sound heard over the left ventricle was unusually abrupt. A murmur was audible over the base. Ordered sodæ salicyl., gr. xx, every three hours till 9 A. M. the next morning; took gr. cxx, when, the temperature having fallen to 98°, it was discontinued. Pulse 160; respirations 40. Mild delirium.

November 8. At 3 P. M. the temperature went up to 102°; pulse 140; respirations 40. Sodæ salicyl., gr. x, every three hours. Delirium very violent; and, after taking three doses of the medicine it was again discontinued, as it seemed to cause the delirium, which continued to increase till 4 A. M., when the patient gradually sank into a comatose state (pulse 160; respirations 40; temperature 103°), and continued so till 7 A. M. on the 10th, when he died. One hour before death his temperature suddenly went up to 106.6°. The heart sounds remained unaltered throughout. While comatose there was no evidence of paralysis. Pupils equal, dilated, did not react to light. Respirations whiffing and shallow.

Autopsy, thirty hours after Death.—On removing the sternum and opening the pericardium, three ounces of clear, straw-colored fluid escaped. There were old and strong adhesions stretching from the pericardium to the heart, chiefly to the anterior aspect of the right ventricle and septum, and a few bands at the apex of the heart and right auricle. No evidence of recent inflammation. Weight, eight ounces. On opening the right ventricle and removing a small, dark clot, the valves and endocardium generally appeared healthy. There was marked bulging of the septum into the cavity of the right ventricle. On opening the left ventricle, the walls were seen to be greatly hypertrophied, and the cavity dilated. No alteration visible in the muscular structure. The aortic valves were very much thickened, but without roughening or abrasion of the edges. At the base of the valves was a small atheromatous abscess, about the size of a split pea, which had obviously burst; some gritty matter could be made to ooze from a rent in its wall. There was a small and similar open ulcer situated just at the base of the anterior aortic valve. The anterior cusp of the mitral valve was very much thickened, and a few small, warty growths were found at the margin. The aorta was speckled over with atheromatous patches for half an inch above the valves. Lungs: Marked hypostatic congestion; old pleuritic adhesions of left lung to pericardium. Small caseous and calcareous masses in both apices. Spleen, soft and friable; structure apparently healthy; weighed 10 ounces. Kidneys weighed six ounces each; some small, white, opaque spots were visible on the surface of both kidneys. The right had one large white patch, a quarter of an inch in diameter, surrounded by a zone of congestion; the section showed it to be an infarct broken down into pus; three other well-marked infarcts in other parts of the same kidney. The spots on the surface were found to be abscesses. Two small abscesses existed in the pyramids. The left kidney contained only one infarct of large size; but there were a great many small abscesses on the surface and in the pyramids. Capsule peeled off easily. The urine contained in the bladder was drawn off and carefully examined, but without showing a trace of albumen. Liver slightly fatty, but not markedly so.

It was decided that death was due to pyæmia, consequent upon the escape of softened atheromatous deposit.

A Bristly Boy.

Dr. H. E. Cauty reports, in the *Lancet*, the following singular case which came under his notice recently:—

The patient, a boy ten years of age, was somewhat imbecile, but well nourished. On removing his clothes, the upper part of the back, both shoulders, and down the outside of both arms, appeared covered with short bristles of a clear, darkish, brown-yellow color, acuminated apices, and very clean. These bristles were, at the edges of the group, gradually shortened from their full length of $\frac{3}{32}$ of an inch, until they joined the skin, which was at the junction raised into polygonal flat disks, finally graduating off to the sound, healthy skin of the hands, chest and back. The feeling communicated to the hand on passing it over the shoulders was exactly similar to that of touching a coarse brush, and the bristles gave way under the touch, resuming an upright position afterward. There were a few pink maculæ over the body, and considerable scaly thickening on and around the patellas. Pulse was quick, with nervousness. Bowels confined. Urine free and healthy. Tongue clean. Appetite good. Sleeps well. The bristles were expelled comedones, containing very few immature hairs and very little sebum, drying up into a horny substance. They were tolerably firmly attached, requiring more force to remove them than to extract a well-rooted hair; and when removed they left a small central depression surrounded by a circle of torn epithelium, which retained them in position. They averaged one hundred to the square inch, and had existed over three months. The boy was ordered mercurial aperient every third night, and to be well rubbed with olive oil and a few drops of carbolic acid. A week afterward all these comedones were softer, and those in process of expulsion much more visible. The bowels were now regular. Ordered three ounces of lard and half an ounce of glycerine, to be followed every morning by the benzine lotion. This treatment was continued for two months, when most of the comedones had disappeared. Some few, remaining partially expelled, had inflamed; and there were also some inflamed punctæ where the comedones had been. The lard and glycerine were continued. Three months subsequently, the boy was brought to the hospital, suffering from herpes. The skin where the first crop of comedones had been was found to be perfectly soft, not showing the least trace of their former existence. But the whole surface of the back, which had escaped before, was now covered with slight polygonal elevations, with a minute central spot, as though a comedone was about to appear, or failing to find an exit, had caused slight swelling. During the progress of this case, a solitary comedone made its appearance on the back, and the time of expulsion, from first to last, was six weeks. There appeared to be some family tendency to abnormal sebaceous secretion, as a brother, aged twenty, had his face, ears and neck, quite black with comedones of the ordinary character. The formation of comedones of an extra horny character is not very rare; but their expulsion and retention on the skin, in such quantities, is very uncommon.

Congenital Absence of Anus and Rectum—Fistulous Connection between Rectum and Vagina.

Dr. R. C. Waters contributes the following case to the St. Louis *Medical and Surgical Journal*. The patient, a healthy-looking infant, five days old, was found to present the following condition. The rectum terminated in a *cul de sac*, and the recto-vaginal fistula was situated about half an inch above the lower portion of this *cul de sac*. The vaginal terminus of this fistula alternately contracted and relaxed after defecation, very similar to the sphincter ani after an ordinary evacuation. The deficiency of the rectum, the space being filled with connective

tissue, was estimated, with the aid of a bent probe, to be about half an inch. It was decided to operate at once. A combined grooved director and aneurism needle was introduced into the *cul de sac* as a guide. The integument was then divided through the median raphe and the tissues subsequently divided with a bistoury. The guide was easily reached, and introducing a probe-pointed bistoury, the opening was enlarged. There was considerable hemorrhage, and since the vessels could not be seized, Monsel's solution was resorted to, which effectually checked it. A tampon was introduced and the operation completed for the time. The next morning the tampon had been passed, and with it some fecal matter. Efforts to draw down the rectal mucous membrane and attach it to the integumentary margin of the anus were unsuccessful, and owing to the great hemorrhage that had occurred, dissection was not resorted to. It was decided to employ gradual dilatation. A thermometer case was used for the purpose. The patient living twenty-two miles from the doctor, this part of the operation was entrusted to its grandmother. The dilatations were continued daily for two weeks, and everything was progressing nicely, when the mother concluded that it gave the baby too much pain and discontinued them. The artificial channel degenerated into a fistulous canal, which eventually closed entirely, and the fæces passed through their previous channel. During the two weeks of dilatation, and for a month subsequently, the fæces continued to pass through the artificial channel. Erichsen states that unless you bring down the mucous membrane, the operation will fail, on account of fistulous degeneration of the canal. He did not want to use Monsel's solution in this case, on account of its interfering with this bringing down of the mucous membrane, but was compelled to resort to it as the only means of checking what threatened to be dangerous hemorrhage. After the operation the patient suffered from shock, but rallied, and was doing well until the cessation of dilatation, though Dr. Waters imagines that the fistulous degeneration which did occur might possibly have taken place at any time after the cessation of dilatation, when the mucous membrane was not brought down. The patient died a year later, from cholera infantum.

"Alkapton" in Urine.

Dr. George C. Armstrong presented to the Medical Society of the College of Physicians of Dublin (Dublin *Journal of Medical Science*) the following novel case. The specimen of urine was from a little girl, apparently in perfect health, whose mother he had attended three years before, in the worst puerperal convulsions he had ever seen. The mother remarked that the child's urine, although perfectly normal in appearance when first passed, on being allowed to cool assumed a deep color, and stained the child's linen. He sent some of the urine to Professor Tichborne, who had made the following analysis:—

The specific gravity at 60° Fahr. was 1.025. Albumen absent. Acid to test paper, and on standing it gave a slight deposit, consisting of urate of ammonia and a little mucus. The urea was scanty, not sufficient to account for the high gravity—being only one half per cent. or 5.25 grains per fluid ounce. This urine presented a great peculiarity; it contained a substance which is only met with occasionally, and which has been termed "*alkapton.*" Bödeker met with a case, and Lionel Beale records another. It behaves like sugar, reduces copper, and probably may be viewed in a somewhat similar light pathologically. Estimated as a sugar it would give about eight grains to the fluid ounce. The urine was examined for bile reactions, but gave none. Dr. Armstrong put some of the urine into small bottles, and, having hermetically sealed them, left one exposed to light and put the other in a dark place. The latter specimen after six hours was not changed in any way.

The term *alkapton* is, it is presumed, derived from *alkali*, *ἁπτω* (fasten or bind), from its relation to alkalies; but the word conveys no real information, and was given at a time (1861) when the physiological chemistry of the urine was imperfectly understood. From various considerations it was thought probable that the peculiar substance in the urine exhibited belonged to the "aromatic series" of chemical compounds, the physiological relations of which group have been investigated with remarkable success during the past five years. The opportunities for observation of this abnormal condition have been too limited to predicate any doctrines concerning its pathological significance.

Hyoscyamia as a Depressor Motor.

The London *Medical Record* says that Dr. Seguin has recently published some valuable observations on this subject. He has used it in paralysis agitans, and choreiform affections with very striking results. In a case of paralysis agitans of four years' duration, where the patient had been under the care of several eminent specialists, and had received, without benefit, a great deal of treatment, including sedatives, counter-irritants to the spine and hypodermic injections of strychnia, he ordered the following formula:—

℞. Hyoscyamiæ (Merck's cryst.), gr. j
Glycerini,
Aquæ destillatæ, āā ℥c
Acid carbol. pur., gtt. ss. M.

Mix, filter with care, and label "Hyoscyamia solution for hypodermic use, ℥j = $\frac{1}{200}$ grain."

The patient was given an injection of four minims ($\frac{1}{50}$ gr.), and half an hour later all tremor had ceased, the mouth was parched, and the pupils were dilated. An hour after there was great dimness of vision, extreme dryness of the mouth, and slight delirium. Four hours after the injection these symptoms had in a great measure passed away; but the hands were still absolutely quiet, and the tremor only very gradually reappeared during the ensuing two hours. On subsequent days, three or four minims were injected, with invariably the same results. In a week, so much tolerance had been produced that this dose did not produce the disagreeable

symptoms, though it did su pend the tremor for from two to four hours. Digestion was not impaired and no irritation was produced at seat of puncture. After six weeks of this treatment, pills containing $\frac{1}{30}$ of a grain were subtituted for the injection, with equally good effect. Two pills daily gave several hours of absolute freedom from tremor, without any toxic symptoms. A month later the patient became more sensitive to the drug, when the dose was reduced to $\frac{1}{30}$ of a grain in the morning and $\frac{1}{60}$ in the afternoon. The paresis of accommodation varied somewhat from time to time, but was readily corrected by weak convex glasses. The patient was discharged after four months of treatment, greatly benefited. In other cases equally good results were observed, $\frac{1}{50}$ of a grain in the forenoon and again at bedtime, being sufficient to almost arrest the trembling for from one to three hours. In none of the cases, however, was the improvement permanent, for after a few weeks, on omitting the drug, it was observed that the tremor was as before.

In two cases of chronic chorea, hyoscyamia proved most beneficial, but failed to effect a cure in one case, where the patient died suddenly, from uræmic convulsions, while the termination of the other case was not recorded. The therapeutic uses of this drug are summed up as follows:—

1. It is a mydriatic. 2. In small doses, it reduces the cardiac pulsations, and increases arterial tension. It may cause a fall of temperature and may produce a rash. It often gives rise to hallucinations and delirium. 3. In large doses, it increases the pulse rate, produces partial paralysis, and induces sleep. 4. It is indicated in mania, restlessness, delusions of persecution, dementia with agitation and destructiveness, epileptic mania, insomnia, status epilepticus, chorea, paralysis agitans, hysterical spasms, tremor, neuralgia, etc. 5. In mania and allied states, it induces sleep with great certainty. 6. In the status epilepticus, it shortens the attack materially. 7. It is a diuretic. 8. Its curative power is not great, and in most spasmodic diseases it is only a palliative.

Dr. Seguin suggests that, in cases of very acute chorea, where death is threatened by incessant motion, hyoscyamia may prove of benefit by securing muscular relaxation with certainty, thus allowing the patient to rest, and giving time for other remedies to act.

Syphilis Treated by Subcutaneous Injections of Mercury, Peptones, and Ammonia.

We read in the *Concours Médical*, January 14th, 1882, M. Martineau, wishing to make a series of experiments with peptones, and mercury, procured a carefully prepared solution containing —

Bichloride of mercury,	150 grains
Dry peptones,	225 grains
Pure chloride of ammonia,	225 grains.

This he mixed with a variable proportion of water and glycerine, according to the concentration desired. M. Martineau has applied this treatment to a great many patients, having up to the present time administered some thirteen hundred injections. He first gave, every third day, an injection containing $\frac{1}{30}$ of a grain of sublimate; while for the purpose of comparison, another series of patients, were at the same time, and like manner, receiving injections of only $\frac{1}{60}$ of a grain. Meeting with no local symptoms, he next gave these injections every two days, then every day, and finally gave as much as from $\frac{1}{20}$ to $\frac{1}{15}$ of a grain daily. He now uses as high as $\frac{1}{12}$ of a grain without experiencing any trouble, and proposes increasing this dose to $\frac{1}{10}$, or even $\frac{1}{8}$ of a grain, if the preparation continues being well tolerated.

During the course of this treatment no local symptoms have ever been observed, no indurations, nor abscesses; and no salivation has been induced; but care should be had, in giving injection, that it be exactly in the subcutaneous cellular tissue, and the back should be chosen, in preference to any other region, because there the sub-dermic cellular tissue is loose and abundant. In the great majority of cases no pain was produced. Two or three patients experienced a slight burning sensation, which lasted for several hours; while five others only felt some little warmth, which passed off in less than an hour. When pain was produced, it appeared after the first two or three injections, but never continued beyond the fourth. Even when as high as $\frac{1}{15}$ and even $\frac{1}{12}$ of a grain were being given daily, no stomatitis, nor any gastro-intestinal troubles have ever followed. This mercurial solution administered in the form of subcutaneous injections appears to have a more marked and rapid effect on the evolution of syphilitic symptoms than sublimate given by way of the digestive tracts. It will be found of especial value in those serious cases of syphilis where the symptoms are of so threatening a nature that they call for quick and decisive action. This therapeutic process is easily applied, and gives neither pain nor unpleasant symptoms of any kind.

NOTES ON CURRENT MEDICAL LITERATURE.

——Transactions of the American Ophthalmological Society, Seventeenth Annual Meeting, Newport, 1881. An illustrated pamphlet of three hundred and fifty pages. Copies can be procured, upon application to the Secretary of the Society, No. 9 West 35th St., New York.

——Contributions to Orthopædic Surgery, a new system of Surgical Mechanics, by Charles F. Stillman, M.D., comes to us in the form of a reprint from the Transactions of the American Medical Association for 1881.

——Contributions to Orthopædic Surgery, an Aid to the Mechanical Treatment of Weak Ankles and Inverted Feet, by Charles F. Stillman, M.D., of New York, is an illustrated reprint from the *Medical Record*.

——We have received the Sixteenth Annual Report of the Board of Trustees of the Connecticut Hospital for the Insane.

BOOK NOTICES.

A System of Surgery, Theoretical and Practical, in Treatises by Various Authors. Edited by T. Holmes, M.A. Cantab. First American from the Second English Edition. Edited by John H. Packard, A.M., M.D., Surgeon to the Episcopal and St. Joseph's Hospitals, Philadelphia. In three volumes. Volume III, 1059 pp. Philadelphia: Henry C. Lea's Son and Co. 1882.

This makes the second American issue of Holmes' System of Surgery we have recently been called on to notice. A synopsis of this volume will present to the reader its merits in a small space. Part I, including Diphtheria and Croup, has been written by A. W. Barclay, M.D., and revised by J. Solis Cohen, M.D. Diseases of the Larynx, by Arthur E. Durham, Esq., revised by J. Solis Cohen, M.D. Diseases of the Thyroid Gland, by Holmes Coote, Esq., revised by the same. Apnœa, by George Harley, M.D., also revised by J. Solis Cohen, M.D. Part II. Diseases of the Bones, by T. Holmes, Esq., revised by Thomas Markoe, M.D. Excision of Bones and Joints, by the same author, revised by John H. Packard, M.D. Diseases of the Joints, by Athol A. Johnstone, Esq., revised by E. H. Bradford, M.D. Diseases of the Spine, by Alexander Shaw, Esq., revised by E. H. Bradford, M.D. Orthopædic Surgery, by W. J. Little, M.D., revised by Dr. Bradford. Affections of the Muscular System, by T. Tatum, Esq., and J. Lockhart Clarke, Esq., M.D., F.R.S., revised by P. S. Conner, M.D. Part III. Diseases and Injuries of Nerves, by J. Lockhart Clarke, M.D., and C. E. Brown-Sequard, M.D.; Locomotor Ataxy, by J. Lockhart Clarke, M.D.; both revised by Professor Roberts Bartholow. Part IV. Gunshot Wounds, by Thomas Longmore, C.B., F.R.C.S., revised by Hunter McGuire, M.D. Part V. Anæsthetics, by Joseph Lister, Esq., revised by J. C. Reeve, M.D. Amputation, by Joseph Lister, Esq., F.R.S., revised by Charles T. Hunter, M.D., and John H. Packard, M.D. Operations upon the Arteries, and Various Operations, by John H. Packard, M.D. Plastic Surgery, by Holmes Coote, Esq., revised by T. G. Morton, M.D. Minor Surgery, by Thomas Smith, revised by John H. Packard, M.D. Part VI. Diseases of the Breast, by J. Birkett, Esq., revised by Theodore A. McGraw, M.D. Diseases of the Skin, by Arthur Van Harlingen, M.D. On Parasites and the Diseases which they Produce, by G. Buck, Esq., revised by Joseph Leidy, M.D. Venomous Insects and Reptiles, written and revised by the same two gentlemen. Surgical Diseases of Childhood, by T. Holmes, Esq., B. E. Brodhurst, Esq., and Alex. Shaw, Esq., revised by Samuel Ashhurst, M.D. Surgical Diagnosis and Regional Anatomy, by T. Holmes, Esq., revised by John H. Packard, M.D. On Hospitals, by Sir J. Ronald Martin, C.B., F.R.S., revised by Norton Folsom, M.D.

The Study of Trance, Muscle Reading and Allied Nervous Phenomena, in Europe and America, with a letter on the moral character of trance subjects, and a defence of Dr. Charcot. By George M. Beard, A.M., M.D. pp. 40. New York: 1882.

This little brochure is readable and interesting. It is a résumé of the psychology of trance, and contains an account of a contest between the author and Brown, the mind reader. While it possesses no practical value to the busy physician, it will serve to while away an hour or two of leisure.

Transactions of the American Medical Association for 1881. Printed for the Association by Collins, 705 Jayne St., Philadelphia.

This volume of six hundred and eighty-four pages ought to be found in every physician's library. Since it contains the deliberations of the representative body of American physicians, all should be familiar with its contents.

Marriage and Parentage, and the Sanitary and Physiological Laws for the Production of Children of finer health and greater ability. By a physician and sanitarian. pp. 185. New York: M. L. Holbrook & Co., 1882. Philadelphia: E. Claxton & Co.

This is a subject well worthy of much study and thought, but hardly suited to a popular treatise, as the present one is. We regret that the author fails to give his name.

A Treatise on Hygiene and Public Health. In two volumes. pp. 1500. Edited by Albert H. Buck, M.D. New York: William Wood & Co., 1879.

This is an elegant work, that should be possessed by every physician who can afford to buy it. We all now realize how much may be done to prevent disease, and since hygiene teaches us how to make this knowledge available, it becomes the imperative duty of every would-be progressive physician to know something of this science. The work before us is an exhaustive treatise, than which there is no better, and we do most heartily commend it.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

HOW TO CONTRIBUTE TO MEDICAL JOURNALS.

At the last meeting of the International Medical Congress, Dr. Billings, in the course of an address on Medical Literature, enunciated some very valuable rules for medical writers, among which were, "always have something to say, and stop when you have said it." This little sentence contains the embryo of professional writing. We have in this country a class of men who desire, and are ambitious, to see their names in print. It matters not to them whether what they have written tends to benefit mankind or not; if they can only get their article published they are satisfied. Hence, medical journals innumerable have, within the past few years, sprung into existence throughout the country. This is an age of unparalleled progress, and new items of universal professional interest are being daily brought to light. These new points are what the physician desires to know, and from the knowledge of them he derives benefit. By the accumulation of individual clinical experiences do therapeutical measures become established. The science of medicine is not yet a certain science; no absolute laws without exceptions can be laid down. Therefore, it occasionally falls to the lot of every physician in active practice to meet with a case, or some cases, unlike any that have been before reported. Now, then, is his opportunity! If he meets with a strikingly novel case of disease, or if he has some unusual experience with either well-known or new therapeutic measures; or if he meets with some remarkable surgical case; or if he discovers *conclusively* some more potent method of treating any particular diseased condition than that hitherto in use, he will benefit mankind and advance his chosen science by making his observations public through some medical journal. But let him be sure, beyond any possibility of doubt, that he has something *new* to say; let him say it as concisely and briefly as possible, and stop when he has *finished*. Long theoretical dissertations or quotations from text-books are objectionable. If he meets with a case of disease that has run a very unusual course, terminating in death, and that may seem to him very interesting, he ought not to report it, unless he has been able, by post-mortem examination, to verify or falsify his ante-mortem diagnosis. Since without this necessary adjunct the bare narration of the symptoms, hypothetical diagnosis and treatment will leave the reader in as much doubt when he has finished reading as the author was when he commenced writing. Therefore, if you desire to prepare valuable communications for medical journals, you must observe the following rules:—

1. Be positively sure you have something *new* to contribute.
2. Tell it in as few words as possible.
3. Do not plagiarize from text-books.
4. Never report an uncertain case, without a verification or falsification of the diagnosis by a post-mortem examination.
5. Do not send the same communication to half a dozen journals. Select one and send it to no others. If you neglect this rule, your habit will ultimately be found out, and *all* journals will reject your communications.

THE INFLUENCE OF ALCOHOL ON DISEASED CONDITIONS.

A large volume could be written on this subject, but a few words will serve our present purpose, which is to call the attention of physicians to the great influence that the use of alcohol may have on various diseased conditions of the human system. The effects of alcohol have been frequently, and we might say, exhaustively discussed, and as a result, when we distill all the arguments, pro and con, we are forced to believe that, to say the least, alcohol is not of any particular benefit to healthy mankind. There are certain conditions of ill health, it is true, in which it may and does do good, but the weight of evidence is in favor of the doctrine that, in the large majority of cases, it is only productive of harm. We all know that a large majority of men use alcoholic drinks as ordinary beverages, and without themselves realizing how much they drink, many of them will daily consume at least a pint of whisky, who consider themselves, and are generally regarded, as only *moderate drinkers.*

No doubt (we speak from experience) many physicians have had, from time to time, presented to their notice instances of chronic disease in which remedies that ought to produce certain effects have failed to do so, and they wonder and cannot comprehend why this should be so. May it not, in many cases, be due to the counteracting influences of even moderate alcoholic indulgence? For illustration, let us select nasal catarrh. Here we have a congestion of the mucous membrane of the nasal passages. Alcohol has a tendency to produce congestion of all the cranial contents. Suppose you may use all the most approved astringent remedies to contract the dilated vessels and remove this nasal congestion, and at the same time the patient continues to use alcoholic drinks; you will have a hard road to travel; it will be like trying to fill a bucket with a hole in the bottom; your astringent efforts will be overcome by the congesting influence of alcohol.

Again we might instance chronic gastritis (which is often produced by the inordinate use of alcohol); your remedies, though well directed, may fail to afford relief if the patient continues the use of alcohol. We all know, for sure, this much, anyhow, that alcohol is a local irritant, and we know that local irritation means a congestion of the part so irritated; therefore, when alcohol is taken into a congested stomach, you may use all the remedies in the pharmacopœia, yet this irritation and congestion will persist, since it is constantly being produced. We might go on indefinitely, illustrating our argument, but it is unnecessary.

Our purpose has been merely to direct your thoughts into the channel indicated, and to cause you to think that chronic disease may be maintained in many cases by the use of alcohol. When you meet a chronic disease that does not yield to your well selected remedies, and when you are at a loss to account for this failure, inquire into the tippling propensities of your patient. Do not be satisfied when he tells you that he is a "*moderate drinker*," but peer minutely into his habits, and learn what moderation means in his particular case.

In some, moderation means a pint or two of whisky daily, or forty glasses of beer; while to others four or five ounces of whisky would constitute excess. This is a collateral consideration in the treatment of disease, not to be overlooked, while attention to it will surely aid much the remedial action of drugs.

Notes and Comments.

Artificial Anus from Tying the Bowel with the Umbilical Cord.

Dr. Latimer reported the following unique case to the Clinical Society of Maryland, *Maryland Medical Journal.* He was called to see a newborn infant, that had been delivered by a homœopath, who, for some reason, had applied a ligature to the cord three successive times. The last time, some protrusion of the intestine had occurred and this had been included in the ligature. The result was sloughing, and the formation of an artificial anus at the umbilical opening, the lips of which protruded, and from them gas and fecal matter escaped. Five days subsequently he found about six inches of the bowel invaginated in the opening and lying out on the abdomen. It was reduced with difficulty and only after incising the upper part of the aperture. The child died the next day.

The Pre-Cancerous Stage of Cancer.

Mr. Jonathan Hutchinson makes some valuable remarks on this subject in the *British Medical Journal*. He believes that if properly treated in its incipiency there is a very good prospect of curing many cases of cancer. "Too late! Too late!" is the sentence written but too legibly on three fourths of the cases of external cancer concerning which the operating surgeon is consulted. The bitterest reflection of all is, that usually a considerable part of the precious time which has been wasted has been passed under professional observation and illusory treatment. He never loses an opportunity to enforce the doctrine of the local origin of most forms of external or surgical cancer and the paramount importance of early operation. All suspicious sores should be considered syphilitic, and treated internally by iodide of potassium, and locally by caustics, until the diagnosis becomes clear. In most cases of cancer of the penis, lip, tongue, skin, etc., there is a stage, often a long one, during which a condition of chronic inflammation only is present, and upon this the cancerous process becomes engrafted. Phimosis and the consequent balanitis lead to cancer of the penis; the soot-wart becomes cancer of the scrotum; the pipe sore passes into cancer of the lip; and the syphilitic leucoma of the tongue, which has existed in a quiet state for years, at length, in more advanced life, takes on cancerous growth. A general acceptance of the belief that cancer usually has a pre-cancerous stage, and that this *stage* is the one in which operations ought to be performed, would save many hundreds of lives every year. What is a man the worse, if you have cut away a warty sore on his lip, and when you examine sections microscopically you find no nested cells? You have operated in the pre-cancerous stage, and have probably effected a permanent cure of what would soon become an incurable disease. Instead of looking on while the fire smoulders, and waiting till it blazes up, we should stamp it out on the first suspicion. He does not wish to offer any apology for carelessness, but he has not in this matter any fear of it.

Poisoning by Stramonium.

In the *Canada Lancet* Dr. Casey A. Wood reports a case of poisoning in a little girl, five years of age, from eating the seeds and surrounding albuminous pulp of the datura stramonium. She presented the following symptoms. She first complained of great dryness in the throat and burning at the roof of the mouth. Shortly afterwards she became very thirsty, but seemed unable to swallow the water that was offered to her. This was followed by nausea without vomiting; twitching of the muscles of forearm and legs; soon after which she became delirious; followed by unconsciousness and convulsions. Eyes bright and glistening; conjunctivæ red and injected, pupils widely dilated, and insensible to light. She would talk rapidly and incoherently for a time, and then burst out into laughter. The skin of the whole body was dry, felt hot, and was of a deep, bright scarlet color. Temperature normal, pulse small and accelerated. A strong purgative of calomel and rhubarb was administered, followed by a large rectal injection of linseed tea and castor oil. This produced several copious movements. They relieved her, and with the last one she passed three or four half digested stramonium seeds. For six hours she was given, every hour, five grains each of chloral hydrate and bromide of potassium, without any effect. She then received a hypodermic of $\frac{1}{10}$ gr. muriate morphia. Three-quarters of an hour afterwards she fell into a troubled sleep, which lasted all night. The next morning she was still nervous, with a red, flushed face, twitching hands and widely dilated pupils, but perfectly conscious. The nervous and other symptoms passed off during the day, but the mydriasis lasted all that day, the next night and part of the following day, when she seemed as well as ever.

Inoculation for Typhoid Fever.

Dr. T. H. Buckler writes to the Boston *Medical and Surgical Journal*, suggesting the inoculation of children for typhoid fever, as well as for the various tubercular diseases. After discussing and demonstrating the great fatality of typhoid fever, he goes on to say that by introducing the germs of this disease into the system, a simple continued fever might be produced, which would confer immunity from the disease thereafter. He claims to have seen five cases, all in one group, where continued fever was evidently produced by the patients having swallowed the morbid poison of typhoid disease. In all, a mild typhoid fever, of the adynamic type, ran the usual course of twenty-one days. [While this proves nothing more than the fact that five persons exposed to the typhoid poison had mild attacks of the disease, while five others equally exposed might have had fatal seizures, which we all know already, yet this communication suggests investigation as to whether typhoid inoculation or vaccination is a possibility.—Ed.]

Abscess of the Pancreas.

Dr. John Shea reports a case of this rare disease, in the London *Lancet*. The patient, a woman, aged 29 and married, commenced (fifteen months previous to her admission to the hospital) to suffer from pain in the region of the liver, increasing gradually in severity and shooting in character. Appetite poor; urine normal; bowels regular and fæces dark. On admission, great tenderness over gall bladder, and jaundice; lungs and heart normal. Under alkaline treatment, with pills of enonymus and henbane, she recovered rapidly, so that in a week she was able to go out. At the end of another week she was quite well, but very weak. In a few days, however, pain over the gall bladder returned, with nausea and vomiting of dark bilious matter, and jaundice. Sinapisms and effervescing medicine were resorted to. Bowels were moved freely, but she continued to grow worse, and lapsed into unconsciousness. All medication proved fruitless, and she soon died. At the autopsy the liver was found large, pale and soft. Pancreas enlarged and hard, being the seat of an abscess, containing pus. A round worm, seven inches long, was found folded upon itself, lying in and obstructing the pancreatic duct, the larger portion of the worm being in the duodenum. Heart somewhat large and fatty. All other organs fairly normal. This case is interesting, particularly in directing our attention to this organ as the seat of some of those obscure cases of disease for which we find it so difficult to assign a cause. Unfortunately, the diagnostic points of disease of this organ are far from accurate, so that in the majority of cases a post-mortem is the only means of making a positive diagnosis. At the same time it is a fortunate thing that affections of this organ are extremely rare.

Ovariotomy.

In the course of a case of ovariotomy reported in the Boston *Medical and Surgical Journal*, Dr. Walter F. Atlee thus summarizes some of the points necessary for success in this operation, with which he has had so much experience as to entitle his remarks to great consideration. In order to avoid any delay, he gives written directions to the patient to have ready—

"Two basins, a bucket, a tin cup, a small tub, a pitcher of hot water, towels, cotton, or carbolized tow, one and one-half yards of flannel, large pins, a package of patent lint, ice, brandy, a feeding cup (or a glass tube, bent), one ounce of chloroform, eight ounces of ether, bottles of hot water, adhesive plaster and a patent ironing table." The patient must have on a night dress and warm woolen stockings. The day before the operation, a dose of castor oil is to be given, and nothing to eat afterwards, only barley water. On the morning of the operation, an enema of warm water is given. In performing the operation, the patient, having her night dress drawn up above the waist, her feet protected by woolen stockings and her lower limbs covered by a double blanket, is placed upon a patent ironing table, which being just large enough for the patient to lie upon, allows the greatest liberty to the surgeon and his assistants. The table is covered with blankets, to make it comfortable for the patient. The knees and elbows are secured by a roller bandage, so as to prevent struggling. A rubber blanket with a large central opening is then thrown over the patient, the edges of the opening being secured to the abdomen by soap plaster. Ether and chloroform, principally the former, are used to anæsthetize. The patient is now ready for the operation. The carbolic spray is not used, but the raw surface of the pedicle is cauterized with carbolic acid. The sponges are washed in carbolized water. A tablespoonful of brandy is given just before the etherization is commenced. If there is much pain or restlessness after the operation, a pill containing $\frac{1}{8}$ grain valerianate of morphia is given and repeated, if necessary, once or twice on the succeeding day. The diet should consist of milk and beef tea. Dr. Atlee, orders the beef tea to be made as follows: one pound of lean beefsteak is cut up small and soaked in cold water, then gradually brought to a boil and boiled for fifteen minutes, then skimmed, strained, and seasoned.

Grindelia Robusta.

The committee on Therapeutics of the Medical Society of the County of Kings, Brooklyn, N. Y., have just made to the Society a report on this drug, published in full in the journal of the Society for ary, 1882, from which we extract the salient points. Nine cases of asthma were reported in which this drug gave marked relief when all other medicines had failed, while ten cases were reported in which it failed to give any relief whatever. During two months, every case of bronchitis, whether acute or chronic, or in phthisical patients, in St. Peter's Hospital, were given the drug, with the result that expectoration, cough and respiration were usually favorably modified, but not in a degree markedly different from the effects of various other treatments. Frequently the medicine would, after a few days, produce headache, and

would have to be suspended, though it was usually well borne by the stomach. The preparation used was Squibb's fluid extract, in doses of from ℥xv to f℥ss, and the conclusions seem to be that this drug does not possess any therapeutic value in asthma, superior to that of the drugs in ordinary use.

Smallpox Pustulation in the Fœtus in Utero.

Dr. Richard H. Day, of Louisiana, makes the following remarks on this subject in the *Maryland Medical Journal:* He reports a case that came under his observation many years ago. A number of cases of smallpox occurred among a colony of slaves, some mild and others confluent; among the latter was a colored woman, some thirty years of age, who was near the end of gestation. She gave birth to her child some ten or twelve days after the eruptive stage of the disease, and within from two to three weeks of her full term. The fœtus was evidently living up to within a short time of its birth, as the mother had felt its motions distinctly within a few hours of its delivery; and when born there was no appearance whatever to throw discredit upon the mother's statement; but the spectacle presented was a sickening one. A fœtus covered with a full and distinct crop of smallpox pustules, from head to foot, some of them already ruptured, and the excavations filled with pus, and many still unruptured, so characteristic as to mark the true nature of the eruption at first sight. The mother recovered.

Carbolic Acid in Diphtheria.

Dr. Z. T. Magill, of Lincoln, Mo., contributes to the Chicago *Medical Journal and Examiner*, January, 1882, the following method of treating diphtheria, from which he has secured better results than from any other. He uses an ordinary hose, from three to five feet long and about one inch in diameter. One end is placed over the spout of a common tea kettle, into which has been put half a gallon of water and half an ounce of carbolic acid. The kettle is then placed on the stove, over a good fire, and when the water reaches the boiling point, the free end of the hose is carried under a blanket thrown over the patient's head. The room must be closed. In a short time the patient will perspire freely. If persevered in at short intervals, breathing becomes softer, and presently, after a succession of quick expulsive efforts, the patient throws off a coat or tube of false membrane. The acid vapor seems to prevent the re-formation of exudation. Alcohol and sulphate of quinine are used in conjunction with the acid, for their supporting properties.

Sulphide of Carbon and Iodoform in Phagedænic Ulceration.

From the *Revue Médicale* we note that Dr. J. Chéron, at the Hospital of Saint Lazare, employs the following solution: Sulphide of carbon, 30 parts; iodoform, 5 parts. Iodoform dissolves readily in carbon sulphide, and the rival odors are mutually weakened by association. The pain is less severe than when the sulphide of carbon alone is applied, and it ceases as soon as the liquid has evaporated. It is best applied with a glass brush. Dr. Chéron has seen cicatrization speedily result in cases which had proved rebellious to all the usual treatments.

Nits in the Hair.

From the London *Lancet* we note the two following methods of removing nits from the hair:

1. Apply spirits of wine freely, so as to dissolve the glue which attaches the nits to the hair, and then wash them away with soap and water.

2. Apply to the hair rather a strong decoction of larkspur seeds (Delphinium staphisagria). This will kill the parasites very quickly. Wash the head with carbolic soap, after two or three days. The nits will then readily come away by brushing and combing.

Iodoform in Orchitis.

The following formula is recommended in orchitis by the *Union Méd.* Iodoform four and vaseline thirty parts. Frictions are to be made with this on the painful testicle in orchitis and neuralgia of the cord, supporting the organ by a suspensory. If mercurial ointment has been previously used, it must be carefully washed off, lest the iodide of mercury, which is a caustic, might be formed.

Pulmonary Gangrene and Death Caused by a Panicle of Grass.

Dr. J. Magrath reports in the *Lancet* the case of a boy of seven who swallowed a panicle of grass. He died twelve weeks subsequently, after much suffering. At the autopsy, it was discovered that one-third of the lower lobe of the right lung was gangrenous; the gangrenous mass was riddled with cavities, in one of which lay the head of grass, blackened, but scarcely altered in consistence. The bodies of two of the dorsal vertebræ were excavated and carious.

Removal of the Whole Uterus, for Cancer.

Sir William Mac Cormac (London *Lancet*) recently removed the entire uterus, for cancer. A cancerous mass involving the cervix uteri, together with a tumor pressing on the rectum, were discovered. Upon abdominal section, the pelvis was found blocked by a tense, fleshy, everywhere adherent cyst, which compressed the rectum against the sacrum and completely concealed the uterus and its appendages. The cyst, which was probably ovarian, contained very offensive pus. The cyst, uterus and ovaries were removed. The vagina was not stitched up. A large double-barreled T-shaped drainage tube was inserted, the end projecting from the vagina, and left in the abdominal cavity; it was used frequently for irrigation. Five days after the operation there was some evidence of suppuration opposite the lower extremity of the abdominal incision. The already adherent edges of the wound were separated, some pus escaped, and the cavity was washed out daily. There was no general peritonitis, and ten days after the operation a speedy convalescence seemed sure. [In connection with this case, the following will possess interest. Some years ago, Dr. Walter F. Atlee operated upon a fibroid tumor of the fundus of the uterus. The tumor weighed seven pounds; an ordinary ovarioto ny clamp was placed on the vagina, and the whole uterus and ovaries removed. The woman made a rapid recovery, without any untoward symptoms, and in less than three weeks was able to get up and make her own bed.—Ed.]

What is "Bright's Disease?"

Under this heading the London *Medical Times and Gazette* makes the following pertinent remarks: It is, we believe, currently reported and generally believed that an old fogy of the name of Bright, who was connected with Guy's Hospital some years ago, asserted that he had seen a number of patients, all having dropsy, with albumen in their urine, while after death their kidneys were commonly found to be diseased. These symptoms and conditions he grouped together, and to them certain individuals still more silly than himself gave the name of "Bright's disease." But it is evident that this Dr. Bright had no gift of imagination, for he actually worked long and hard before he came to the trifling conclusions above referred to; beyond all, he could never invent his facts, nor had he the gift of twisting them about so as to prove anything. In short, he was what Americans would call a "very or'nary cuss" after all. But see what has been done since his day! Why, his disease, though it is by the weak-minded still supposed to kill a large proportion of our fellow-mortals, has actually been improved off the face of the earth! First, it was found that the same condition of kidney would sometimes give rise to dropsy, and sometimes not; especially this was noted—that in the same individual dropsy might exist at one time, and not at another; so the dropsy was dropped as one of the necessary symptoms. Then it was found that albumen was not always plentiful in the urine; yea, that it was sometimes absent altogether; so the albuminuria has been got rid of as an essential feature in Bright's disease. Only one thing more remained, and that was the kidney disease, which has now apparently gone the way of all the rest; so that we now have the pleasure of contemplating a disease which no longer possesses any one of the characters by which it was originally distinguished. These are great achievements, doubtless; but destruction comes naturally to mankind. Look at the new theories constructed! Some of the wicked ones, we fear, would, with regard to these, say that the zeal which comes not of knowledge might be better employed even in coining words than in building hypothesis on hypothesis—a kind of tower which has little chance of reaching to the heavens, or, indeed, attaining to any greater height than other fungoid growths similar to itself.

The Sensation of Thirst.

Professor Nothnagel contributed a very interesting and instructive article to a recent number of *Virchow's Archiv*, upon which the London *Lancet* comments, and from which we extract the salient points. It is well known that the sensation of thirst expresses an insufficiency in the amount of water in the organism. But why is thirst referred to the mouth and throat? The scanty experimental researches on the subject teach but little. He relates a remarkable case, which throws some light on the question. A man was kicked in the abdomen by a horse, and knocked down, striking the occiput against the hard ground. He was not stunned, but could not walk, on account of the severe pain in the abdomen and back of the head and neck. Previously well, immediately after the accident he began to feel extreme thirst, and in the next three hours drank five pints of liquid. No injury to bone could be detected, temperature was normal, and pupils small. The local pain soon passed away, but the thirst continued. The

thirst was unabated during the three weeks the patient was under observation. It was uninfluenced by treatment, and became more intense every day about noon. Nothing but large quantities of water relieved it, the amount taken daily varying from one to four gallons. The quantity of urine secreted daily was about three-fourths the amount of water taken, and its specific gravity varied from 1.002 to 1.010. The skin was moist. Nothnagel believed that the thirst must have been due to a central effect of the blow on the occiput. The probabilities, he thought, are that the thirst centre is located in the pons or medulla; though this is only speculation, since there were no symptoms sufficiently distinctive to accurately locate it.

Recurring Lethargy.

The *Lancet* records an interesting case that has been under observation at the Hospice-Général, Rouen. For twenty days a woman, thirty-seven years old, has been in a profound sleep, which is broken every night for a few minutes, when she takes food. The sleep is accompanied by general rigidity. Her first attack was fourteen years ago, and periods of lethargy have since recurred from time to time. During the intervals she seems perfectly well. The onset is always sudden; she goes to sleep in a moment, no matter what she may be doing. Just before the onset she becomes nervous and taciturn. During her sleep the face is well colored and warm, and respiration is regular. About half-past ten o'clock each night the legs begin to tremble, slight groans are uttered, and at eleven she opens her eyes, sits up and eats what is given her, without speaking. She immediately goes to sleep again (the muscular rigidity, however, not reappearing until about four in the morning), and so remains until the next night. On two occasions she has slept for ninety-six hours, without food. She does not lose flesh.

Vomiting of Pregnancy.

At a recent meeting of the Obstetrical Society of Boston (Boston *Medical and Surgical Journal*), this interesting subject was under discussion. Dr. Fifield said that for years he had succeeded in controlling the vomiting of pregnancy, either with bromide of potassium or rectal injections of one-half drachm of chloral hydrate. But recently he had a case under observation in which these measures, as well as others tried, utterly failed to give relief; the trouble growing daily worse, until the woman vomited blood. He then introduced Sims' speculum, drew down the cervix, which was found a little excoriated, and covered it thoroughly with nitrate of silver. Bromide of potassium was then given in ten grain doses every two hours. The next day the patient was well. It was the sense of the Society that the vomiting of pregnancy is due to reflex action.

Hygiene and Public Education.

The *Sanitary Engineer*, commenting on the public school reform of France, by which each department is to have a commission composed of six persons, among whom will be found an architect, a teacher, and an engineer, to whom all plans for school buildings must be referred, says, "It is curious to observe how completely sanitation is ignored in this order." [It is singular that an intelligent nation like France should so neglect this matter of prime importance in the education of her children. This foolish method of training the mind, at the expense of the body, in the light of our present hygienic knowledge, can only be denounced as criminal on the part of legislators, and it really behooves parents to take a hand in the matter, and force sanitary legislation for the welfare of their school children. Let us take an active part in agitating such reform in our own country.—Ed.]

Oral Surgery.

At a recent meeting of the Midland Medical Society, Mr. Bennett May showed a male patient, aged forty years (with specimen), from whom he had three weeks previously removed the tongue, part of the lower jaw, and floor of the mouth in one piece, for epithelioma, some enlarged lymphatics under the jaw being removed at the same time. The patient had made an excellent recovery.

"Our Continent."

Of recent ventures in the field of general literary journalism none has attracted so much attention as "Our Continent." It has made its appearance with little blowing of trumpets, but with an imposing array, not of the names merely, but of the productions of the best writers in America and England. The position it takes is with illustrated weekly journals, but it does not make the reading matter subordinate and inferior to a lot of wood cuts and process engravings. On the contrary, it uses engravings to develop and increase the interest in the reading matter. While in the first instance literary, and hence well supplied with poetry and stories, it is eminently attractive

to the family circle by its admirable departments devoted to housekeeping, social customs, dress, home horticulture, etc., etc. Popular science is also well cared for, and articles on history, biography, etc., are prominent features. Its price is $4.00 a year, and as a family paper it has no superior in our language. For specimen copies, which are mailed free, address "Our Continent, Chestnut and Eleventh streets, Philadelphia."

Special Reports.

NO. III.—INFECTIOUS DISEASES (Continued.)

Diphtheria.

Although we recently presented a special report on Diphtheria, we have so much more of interest that a second one will not be superfluous. We have received from the National Board of Health a supplement to their regular bulletin, containing the report of Prof H. C. Wood and Dr. H. F. Formad on the nature of the diphtheritic contagium, and since their labors have been productive of good results, a résumé of their experiments will be given. Their studies were made from a double point of view, namely, clinical and experimental. The bacteria that are present in diphtheritic membrane are identical in form and size with those which are present in the membrane of a non-diphtheritic trachitis, and in the exudation of an inflamed tonsil. They do not hesitate to affirm that it is not possible to determine, even with the highest powers of the microscope, whether an individual micrococci colony, or a mass of such colonies, have come from the surface of a furred tongue, or from an ordinary case of simple throat inflammation, or from one of a diphtheritic character.

A second question, no less important than that just discussed is, are bacteria always present in diphtheria, or only in some cases? In attempting to answer this question, they examined a very large number of cases. In seven cases of what they term "*endemic mild diphtheria*," observed in Philadelphia, the blood was examined *during life*, and in six cases no fungi were found, while in one case micrococci were somewhat abundant in the vital fluid. At Ludington, Michigan, out of fourteen cases of the *severe epidemic* form of the disease, micrococci were found in seven cases, while in the remaining seven they were absent. The cases in which there were no micrococci were all of them very light, or in the stage of convalescence, and the amount of the fungi present in the malignant cases seemed to be proportionate to the severity of the symptoms, and to steadily progress with the disease in the fatal cases. Therefore, they formulate, as established, the proposition that in *endemic mild diphtheria micrococci are always present in the part locally diseased, but are usually not present during life in the blood or in the glandular organs, even in cases which may prove fatal; that in malignant epidemic diphtheria, micrococci are always present in the part locally diseased, and are also usually, and, perhaps, always to be found in the blood and tissues of severe cases, but are frequently, if not usually, absent from the blood of mild cases.* It is very important to know whether the lymphatics and the blood-making organs are the primary seats of infection or not. They are unable to present clinical evidence on this point, but desire to call the attention of investigators to the matter, and state that in animals they found the spleen and bone marrow especially attacked by the fungus. They cannot conclusively state whether or not micrococci are found in the blood in other diseases besides diphtheria, though they incline to the negative view, since, after making a large number of examinations of blood from persons suffering with various diseases, they were only found in three cases other than diphtheria, and all three cases died, two from scarlet fever, and one in childbed, and suffered from sore throat, that Professor Wagner describes under the name of scarlatinal diphtheritis.

MORPHOLOGY.

Great difficulty is sometimes experienced in distinguishing bacteria from other minute organic and inorganic particles. Certain mycelial threads and vibrios, coagulated fibrin, and protoplasmic and fat molecules, often closely resemble micrococci. In zooglea forms the micrococci can at once be distinguished by an experienced eye, as the micrococci of an individual zooglea mass are always uniformly of one size, and are always at the same distance from one another, in contradistinction to albuminous and fat molecules, which vary in size and are at varying distances from each other. Isolated micrococci may vary in size. Micrococci may arrange themselves in pairs and chains; non-living molecules or granules cannot. Micrococci are not soluble in strong acids and alkalies, nor in alcohol and ether, as are fat and most other molecules. Micrococci take the staining well, particularly with hæmotoxylin and aniline dyes, and the aniline dye cannot be so easily washed out as in the case of animal tissues. Beautiful preparations may be made by simply treating sections with a mixture of glycerin and acetic acid, the micrococci be-

coming yellowish brown and prominent amid the perfectly translucent structures. Tincture of iodine is an excellent staining fluid for bacteria within tissues. If first treated with a solution of caustic potash, iodine stains the micrococci deep yellow, while the rest of the tissue is only slightly tinged. The most important distinguishing point between micrococci on one hand and organic and inorganic particles on the other hand is obtained by culture. Micrococci will always multiply, though sometimes much more rapidly than others. They elongate, divide, form chains or zooglea masses if brought into a suitable culture medium.

If the above-mentioned distinctive points are observed, mistakes in recognizing micrococci and other bacteria are entirely out of the question.

In regard to the question of magnifying powers used in recognition of micrococci they affirm (contrary to statements of some other investigators) that a good one-fifth objective is sufficient for the detection of the diphtheritic micrococci, particularly when appropriate staining is used. They saw no micrococci with a magnifying power of 1500 which they could not detect with an amplification of 500 diameters. For the finer morphological details of micrococci a high magnifying power is required, and they habitually used a one-twelfth Zeiss Homog-Immerson.

They also state that as the result of much experience they are positive that the excessive precautions often insisted upon by authors as necessary in looking for micrococci in the blood, etc., are not, in fact, necessary. Micrococci do not exist in the air to any extent, and exposure of blood slides for a few minutes to the air never is followed by the appearance of micrococci when none have previously existed. This is not true of moving bacteria, which in their early growth they have in some of their former researches mistaken for micrococci, and which may appear rapidly in exposed blood.

A description is then furnished of the methods employed for the artificial cultivation of micrococci, which were used for experimental investigation on animals. In one series of experiments twenty-five cultures were made and all the mentioned culture fluids were tried in this series up to a fourth generation.

The general results of the culture experiment were similar to those of the first series up to the second generation. In the third generation the micrococci already began to fail in growth and multiplication, and the fourth generation yielded a still poorer crop. The cultures were occasionally impure—the rod bacteria supervened.

The regulation of the temperature was sometimes defective during the experimentation with this series, on account of imperfect working of the mechanism of the incubator. Sometimes the temperature fell down to 20° during the night, and it was frequently observed that rod bacteria promptly made their appearance in large numbers during such intervals, and spoiled the cultures. The same occurred with clean cultures when heat was suspended purposely for several days. Those culture tubes, however, which were subjected to a uniform temperature of not below 37° C. did not show any invasion of rod bacteria, and the growth of micrococci continued in the manner described.

The careful measurement of the micrococci in this series, which was best accomplished by measuring the chains of micrococci, revealed a size of $\frac{1}{14000}$ to $\frac{1}{42000}$ of an inch in diameter, the latter size relating more to micrococci in zooglea form. The torula chains were usually made up of the smallest micrococci, approaching in this respect to those of the micrococci balls which they have proven to be formed by the invasion of leucocytes by micrococci.

Some of the experiments performed seem to warrant the deduction that inoculation with materials taken from patients suffering from the endemic mild diphtheria of Philadelphia, frequently produces a secondary or indirect tuberculosis in the rabbit, but very rarely, if ever, causes any disease in the rabbits comparable to diphtheria in man, or even any septic disorder; of course, the experiments do not prove that malignant cases of diphtheria may not occur in Philadelphia and have different relations to inoculation.

The Ludington diphtheritic matter acted as a very deadly poison upon the animals inoculated with it. In three rabbits, portions of the membrane were placed in the trachea, with uniformly fatal results. In three rabbits, membrane placed under the skin or in the muscles acted as promptly as did that inserted in the trachea. The experiments in which the inoculation of membrane had no effect were those in which the poison was placed upon an open surface, where it was liable to be washed off. Such were experiments where the vagina and mouth were selected. In one experiment the membrane was more or less imperfectly retained in position by sewing the eyelid over it, and the result was somewhat doubtful.

In two instances, instead of using membrane, they employed minute pieces of kidney for inoculation, and with precisely the same effect, namely, rapid death, with characteristic lesions.

Injections of minute quantities of blood and saliva into the veins gave, however, entirely negative results, with one very doubtful exception.

It will be seen that the effects produced were entirely different from those which were obtained previously with Philadelphia matter. The results of the two series of experiments may be summed up in a few words, as in the following proposition: *While inoculation of the rabbit with false membrane from endemic or ordinary Philadelphia diphtheria is rarely followed by rapid systemic infection, the placing of material from cases of malignant epidemic diphtheria in the trachea or under the skin is usually fatal; the characteristic post-mortem lesions consisting in the presence of micrococci in the blood, and sometimes also in the internal organs, along with severe inflammation at the point of injury, where there is produced an exudation resembling diphtheritic membrane, and crowded with micrococci.*

With these observations and experiments before us, the question now presents itself, what are the relations of the micrococci which exist in diphtheria to the disease? Are they the poison of the disease? or, in other words, are they capable of producing it? The absolute, final answer to this question can only be made by producing disease in the animal by micrococci isolated from the remainder of the diphtheritic poison. The difficulties to be overcome in such an attempt are very apparent. Still, great as they are, they must be overcome before we can hope to possess any absolutely accurate knowledge of the causative power of the micrococci; before we can determine whether they are the active agents in producing the disease.

It is certain that they produce diphtheritic septicæmia with second generation's culture, and they believe that future research will confirm this, and show that *micrococci cause diphtheria by their power of forcing their way into the tissues and by their own excessive vitality overcoming the vitality of those tissues, changing their nutritive processes, destroying them, and finally getting into the blood itself, destroying its white corpuscles and obstructing the circulation.* While this is their opinion, they do not think that at present it can be considered positively proven that the micrococci themselves are the essential poison, and not simply the carriers of the poison.

Their experiments demonstrated conclusively that after a time the membrane, even if kept perfectly dry, will lose its contagious power.

In finally considering the nature of diphtheria, the facts which have been established should be carefully thought over. They may be stated as follows:—

The micrococci of diphtheria do not differ, so far as observed, from the micrococci of furred tongue, etc., except in their tendency to grow in culture fluids.

The micrococci of furred tongue, or ordinary sore throat, have a less tendency to grow under culture than have the micrococci of endemic non-malignant diphtheria.

The micrococci of endemic or non-malignant diphtheria have a much less tendency to grow under culture than have the micrococci of malignant diphtheria.

The rapidity of growth of the micrococci is in direct proportion to the malignancy of the case yielding them, and its contagiousness.

On exposure to the air diphtheritic membrane of the most virulent type loses its contagious power, and the micrococci *pari passu* lose their power of growing in culture fluids.

Under successive generations of artificial culture, the diphtheritic micrococci lose their growth activity, and also their power of infecting the rabbit.

It has not been experimentally directly proven, but it is a necessary inference from the two facts just stated, that under certain favoring circumstances the sluggish micrococcus puts on growth activity, and, in all probability, *poisonous properties.*

Every grade of case can be found in man, from an ordinary sore throat, through simple pseudo-membranous angina and trachitis, up to malignant diphtheria.

Any inflammation of the trachea of sufficient intensity may cause the formation of a pseudo-membrane.

A case may begin as one of sthenic "pseudo-membranous croup," and end as one of adynamic "diphtheria," with blood poisoning; and in cases of this character not infrequently no exposure to contagion is discoverable, and there is clinically every reason to believe that the blood poison has been developed within the body of the patient. The theory of the disease which they would deduce from these facts is, that the micrococcus which directly or indirectly causes the diphtheria is not a specific organism, different from that common to healthy and inflamed throats, but is an active state of that organism; that certain circumstances outside of the human body are capable of throwing this common micrococcus into this condition of active growth

and engendering an epidemic of diphtheria. When diphtheria is thus epidemic the micrococci light upon a throat, and if the throat have little resisting power, as in the child, inflame it, or increase a catarrh already existing into a violent inflammation, and also rapidly enter the blood and cause systemic poisoning.

On the other hand, a catarrh in a weakly subject may, in the beginning, be simply an inflammation from cold, but the ordinary micrococci in the throat, or mouth, favored by the special conditions, etc., may gradually change from the dormant to the active state, and by and by act upon the throat, and at last force their way into the system, and a self-generated diphtheria be formed out of a "cold."

The essential points of these very valuable investigations have now been concisely stated. Any one who may desire to read the whole report, will find it in full, in the "Supplement to the *National Board of Health Bulletin*," of January 21st, 1882.

Correspondence.

Adherent Placenta—Death from Septicæmia.

Ed. Med. and Surg. Reporter:—

On December 15th, 1879, I was called to attend to Mrs. G. in a case of obstetrics. When I arrived the child was born. In due time I attempted to remove the placenta, as considerable contraction of the uterus was evident, and found it attached, and also hour-glass contraction of the uterus. When I got my hand through the contraction I found the placenta attached, and commenced, with the ends of my fingers, to separate it; the patient struggled and screamed so that I desisted for a short time. My patient began to faint, from loss of blood. In a short time, as I had not removed my hand, I separated the placenta, and removed the whole of it at once;* gave my patient 15 drops fl. ex. ergot, and with application of cold and frictions over the abdomen the hemorrhage was soon checked. In a few days after she took cold and remitting fever, but recovered in a few days.

On the 30th of December, 1881, she again sent for me. When I arrived she was in active labor. Upon examination I found a hip presentation. In perhaps half an hour the child was delivered, to all appearance, dead. As usual in such cases, I put a handkerchief over its mouth and commenced artificial respiration, by filling the lungs with my breath and with slight pressure upon its chest. This I kept up for ten or fifteen minutes when it made attempts to breathe and soon succeeded. Suspecting attachment of the placenta and hour-glass contraction, I attempted to remove the placenta by introducing my right hand into the uterus. I found the same state of things that I did two years before. As soon as I commenced to separate the placenta she put her heels against my arm and gave such a push that I had to let go of the placenta or I would have inverted the uterus, but the cord which I had wrapped around my finger of the other hand was torn off, broken. I then attempted to put her under the influence of ether, but she resisted and pushed my hand away, until I gave that up. After, perhaps, half an hour, she consented to let me again attempt to remove the placenta.

Having fixed myself in such a position that she could not push me back, I made another attempt, and just as I commenced again to separate the placenta, she put her heels up against me and commenced to push me away; but as she could not do that, she screamed at the top of her voice that I was killing her, and my assistant let go of her, and she slid to the head of the bed at the opposite side, so that I had to let go or invert the uterus. I then told her husband to send for another physician, which he did; and in about two or three hours Dr. B. came, and after making a statement of the case to him, it was agreed that I should anæsthetize her, and he should remove the placenta; but, as before, she could not be etherized. Dr. B. then attempted to remove the placenta by piecemeal, but she treated him as she did me: Put her heels against him and forcibly kicked him away, upon which he said there was no use in trying to do anything for her unless she kept quiet. The priest was then sent for, and after attending to her spiritual affairs, she agreed to be put under the influence of chloroform: but after a few inhalations she commenced her struggling again, pushing away my hand and screaming that we were smothering her, and would have thrown herself on the floor if I had not caught her. I then said that they would have to hold her until I would chloroform her; but as her husband and parents seemed to hesitate, and as they let go of her every time when she would commence to struggle, Dr. B. said we had no right to force her, as she was a reasonable being; she had a right to have her own way; in which her parents seemed to acquiesce. Dr. B. and the priest then went home, and I remained with her till morning, when I made another examination. The parts seemed favorably disposed, but she had a bloody, serous discharge, of a very offensive character, after having had a chill a few hours before. She could not be persuaded, and utterly refused to let any more attempts be made, either to be put under the influence of chloroform or let another attempt be made to remove the placenta. She said she would rather die than to suffer every time in having the after birth removed, when she was confined. I told her I would not stay any longer, as there was no use of my staying when I was hindered from doing the only thing that would save her. Dr. W. afterward saw her twice, I believe; but she died of septicæmia on the 2d of January.

The first time this unfortunate woman was confined she had an irregular, who, when he found attachment of placenta, said he would not shoulder the responsibility alone. Dr. Walker, of this place, was sent for. The Eclectic held her and Dr. Walker got most of the placenta re-

* See my article in the Reporter, January 5th, 1870, on attached placenta.

moved by piecemeal, at last. She recovered after having been confined five or six weeks.

E. A. Oppelt, M.D.

Loogoote, Ind., Jan. 22, 1882.

News and Miscellany.

Lorgevity.

The obituary column of the London *Times*, Jan. 24th contained some remarkable illustrations of prolonged existence, in eight persons, viz., five gentlemen and three ladies, whose united ages amounted to 685 years, giving an average of 85 years and 7 months to each. The oldest, as usual, was a lady, who had reached the great age of 93, the youngest of the same sex being 83 years of age; of the gentlemen, the oldest was 90, and the youngest 81 years of age. The same obituary recorded the deaths of ten septuagenarians, averaging 76 years and 1 month each. That a single day's obituary should record the deaths of so many as eighteen persons averaging the patriarchal age of 80 years and 4 months, is most remarkable.

American Illiteracy from an English Source.

The London *Medical Times and Gazette* says: A summary of an official table has been published, giving the statistics of illiteracy in the United States, from which it appears that in New York the percentage of the total population who cannot read is 3.28, in Pennsylvania 3.41, in Connecticut 3.37, in Massachusetts 4.24, in New Hampshire 3.45, in Vermont 3.91, in Rhode Island 6.31; while the figures for Maine are only 2.80. The unfavorable percentage shown in Massachusetts and Rhode Island is stated to be caused by their factory system and the importation of cheap labor from Canada and other parts of the world.

Vaccination Notes.

The Pennsylvania Railroad requires a certificate of vaccination from every laborer in its employ.

The City Council of Richmond has passed, over the Mayor's veto, an ordinance requiring all persons not vaccinated within twelve months to be vaccinated.

Female Doctors in Russia.

The female candidates for entering upon the study of medicine in Russia keep ever increasing. The normal number of admissions is fixed at seventy, but the actual number of applicants now amounts to more than double that number. The total number of female students that have been admitted within ten years have been 959, and of these 281 appear to have terminated their studies, and 152 been admitted to the practice of medicine.

Items.

—A boy nine years of age recently died from the effects of chloroform, administered in the Children's Hospital at Manchester, England.

—Daniel Webster once took a young lady to task for wearing short sleeves, and reflected severely on bare arms. "Why, Mr. Webster," exclaimed the young lady, "I'm astonished that you, the great expounder of the Constitution, should object to bare arms!" "What has my expounding the Constitution got to do with it?" growled Daniel; to which the young lady replied, "Does not the Constitution say that the right to *bear arms* shall not be interfered with?" History does not record the effect of this shot, but Webster died that same year.

—A western paper makes mention of a place in the far West destined to be the "Mecca" of bald-headed men, since, owing to some peculiarity of climate or water, the most luxuriant growth of hair is soon produced upon the baldest heads. This must be truly a most extraordinary place.

—Sir Erasmus Wilson, President of the Royal College of Surgeons of England, has given $50,000 for the purpose of founding a chair of Pathological Anatomy in the University of Aberdeen.

I Pede Prospero.

The following is from the London *Lancet*:—

A glad good morrow to my friend,
Of the great Æsculapius noble son!
To his famed votary, oh send
Success in years to come!

May great prosperity attend
His ceaseless efforts to amend
The suffering and pain and grief
In this sad world. What a relief
To feel that life is spent in doing good!

Though weary oft, take courage!
The noblest aim will triumph in the end,
For youth will bless, and hoary age will lend
A voice to speak thy praise!

Go on and prosper; may each year increase
In joy and hope, till crowned in the end
By well-earned laurels.
Such the good wishes that I fain would send,
With many a glad good-morrow, to my friend.

M. D. M.

QUERIES AND REPLIES.

E. T. S., of Fla., asks for the best local treatment for spinal irritation, to allay pain, etc.

P. O. G.—Fournier's work, entitled, "Syphilis and Marriage;" translated by Dr. Morrow, has been published, and we can send it to you. Price $2.00.

MARRIAGES.

McKNIGHT—LOUNSBURY.—On Wednesday, Feb. 16, at the residence of the bride's parents, Kingston, N. Y., by the Rev. J. G. Van Slyke, assisted by the Rev. Dr. Demarest, Kate DuBois, daughter of the Hon. Wm. Lounsbury, and Dr. Charles Scott McKnight, of Plainfield, N. J.

VESTAL—PRIDE.—On Tuesday evening, Feb. 14, 1882, at the house of the bride's mother, Mrs. Letitia Diffenbaugh, by Rev. J. D. Boone, of Morrelton, Arkansas, V. S. Vestal, M.D., and Miss Nannie E. Pride, all of Dripping Springs, Arkansas.

DEATH.

BRIDGES.—On the 20th inst., Robert Bridges, M.D., Emeritus Professor of the College of Pharmacy, in the seventy-sixth year of his age.

☞ No preparation of COD-LIVER OIL equals, in elegance and efficiency,

BAKER'S EMULSION

50 per cent. Oil with Hypophosphites of Lime and Soda.

NEW (1881) CROP of Pure Cod-Liver Oil, now arriving via Throndhjem, [illegible], per steamer.

DR. JOS. LEIDY, Professor of Anatomy, University of Penna., says: Gentlemen: It affords me pleasure to have the opportunity of recommending your Cod-Liver Oil to the medical profession. I feel satisfied that a purer and more efficacious article cannot be obtained in the market.

DR. RICHARD O. COWLING, Louisville, says: "We employ BAKER'S COD-LIVER OIL in preference to all others. The Pure Oil is palatable and digestible, and the emulsion is well-nigh delightful."

ABSOLUTE PURITY AND FRESHNESS GUARANTEED.

AGENTS FOR

An Astringent and Balsam combined, in the most convenient form for application. Descriptive circular and endorsements mailed on application. Boxes of 14 Suppositories, 75 cents, by mail, to Physicians who mention this Journal.

JOHN C. BAKER & Co., Philadelphia, Pa.

1180-eowtf

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

CONCUSSION OF THE BRAIN.

Delivered before the Paris Faculty of Medicine,

BY M. DUPLAY,

Professor of Surgery.

Gentlemen—The further we advance in the study of cerebral lesions, the more difficult our task becomes, and the more interesting the subject.

We have studied together the wounds of the scalp, and the traumatic lesions of the subjacent cranium; we have been fully satisfied, too, in concluding these researches, that we have established clearly the intimate relations existing between these lesions and the symptoms observed.

We are to consider, to-day, a more delicate subject, those traumatisms which have a direct influence on the brain itself; for, besides the direct wounds with which we are already conversant, the brain may be affected in various ways by traumatic lesions; in a word, there may be concussion, or contusion, or compression of the brain.

The older surgeons were but little conversant with the lesions of this organ of which I am about to speak.

The first attempt at a symptomatic description of cerebral concussion was made by Boirel, in 1677, who tried to separate it from the other lesions of the organ. This distinction reappeared in the works of Sabourand and J. L. Petit, and was definitely accepted by the old Académie de Chirurgie. Later, Boyer, and particularly, Dupuytren, established, in connection with concussion and compression, the symptomatology of contusion of the brain.

But, if this division of cerebral lesions, established by men eminent for clinical observation, appeared to respond to as many clearly separated morbid conditions, the symptoms were not fixed, nor the lesions clearly defined, and this part of surgical pathology, together with its pathological physiology remained exceedingly obscure.

It is only within the past few years, through the remarkable advance in our knowledge of the pathological physiology of the nervous centres, due to well-directed observation and experimentation, that it has been possible to define anatomically and characterize by symptoms peculiar to each, the different traumatisms of the brain. Among the more important modern works must be cited that of M. Duret, prosector to this Faculty.

CONCUSSION OF THE BRAIN.

Concussion of the brain is characterized by a special collection of symptoms, consisting in an alteration, more or less marked, of intelligence, sensibility and movement, which supervenes immediately after the injury, and presents this peculiarity, that if death does not immediately ensue, all the morbid symptoms gradually disappear. For a long period it was generally admitted that this set of symptoms had no connection with any appreciable lesion, and resulted simply from the shock sustained by the encephalic mass; but these hypotheses of transmitted oscillations and vibrations are at present almost abandoned, and we will see, as we progress in our study, that modern works tend to explain differently the phenomena of concussion. Perhaps, then, it will be possible to complete this purely symptomatic definition of concussion.

Concussion is said to be direct when the injury affects the cranium itself; indirect when it supervenes after a fall on the feet, the knees, the pelvis, or the face.

The symptoms attributed to concussion are multiple and complex, and have been divided into three classes, somewhat arbitrarily separated, and based on the gravity, more or less marked, of the functional derangement. In the first degree, or slight concussion, following a blow or fall, the patient is giddy and confused; there is ringing in the ears; vision is disturbed; the face suddenly becomes pale; respiration is one moment arrested, and the individual becomes faint and weak. Then, after a very short time, a few seconds, or a few minutes, rarely more than a quarter of an hour, the patient comes to himself and has but a very vague recollection of the accident; there remains, however, some dullness of comprehension, and a sensation of great fatigue, which may last but for a short time, or for several hours.

The gravest degree of concussion follows a more violent traumatism, and is characterized by the following symptoms; the patient falls insensible and motionless; he remains in a state of coma; pulse and respiration are hardly perceptible; the evacuations are involuntary, and death supervenes promptly, by a sort of gradual extinction of the action of the heart and lungs.

Between these two extreme degrees there is one intermediary, called grave concussion, of which the symptoms differ widely, according to the intensity of the traumatism: loss of consciousness, more or less complete abolition of general and special sensibility, complete muscular relaxation, dilatation of the pupils, involuntary evacuations, while the face is pale, pulse very small and slow, respirations few and far between. In some cases there have been but twenty pulsations per minute.

After a few hours or a few days the morbid symptoms become less intense, but the return to the normal condition is gradual and very slow. Generally the intellectual faculties are reëstablished more slowly than the motor and sensory functions; this is an important point to bear in mind. The patient remains for some time confused, the memory particularly being defective.

I have passed very rapidly, gentlemen, over the symptomatology of concussion, which you will find well and completely considered in your works on external pathology, as I wish to arrive at the less known and more interesting part of the subject.

ANATOMY AND PHYSIOLOGICAL PATHOLOGY OF CONCUSSION.

To what anatomical condition does this set of symptoms correspond? This question has long remained unanswered. As the autopsies of patients who succumbed in this state revealed no lesions to Littré, Sabatier, Boyer, or Meunier, it was considered that cerebral concussion consisted in the shock sustained by the brain in all its parts, without any appreciable lesion except the close packing together (tassement) of the nerve fibres.

Gama even sought to prove the correctness of this doctrine by experimentation; he poured isinglass into a thin globe of glass, and then by percussion obtained oscillations of the diffluent mass, which he compared with the oscillations of the brain in concussion. As if the brain, incompressible and adherent at certain parts, divided into hemispheres and lobes separated by tense networks of fibrous tissue, presented any analogy with a diffluent mass of isinglass.

Then other authors, with Deville and Prescott Hewett, brought forward cases in which lesions were found at the autopsy, a rachidian hemorrhage in Deville's case. Somewhat later, Fano, having instituted experiments, which consisted in suddenly killing dogs by a blow on the head, and having always found hemorrhagic effusion at the base of the cranium, concluded that concussion does not take place, and that the symptoms ordinarily ascribed to it are due not to concussion, but to a contusion of the brain, or to hemorrhagic effusions situated principally at the base, and inducing compression of the bulb.

In fact, all these suppositions were far from conclusive, and opinions on the subject were extremely vague. Our ignorance regarding the nature of concussion was almost complete. This was the state of affairs when I composed my treatise on surgery; nevertheless, as clinical observation compelled me to admit the existence of concussion as an affection proper to the brain, I was opposed to its exclusion from the list of diseases of this organ. I also expressed the opinion that research should be directed toward the bulb, to find the material lesion of concussion. I considered also, that a shock might determine "a sudden and more or less persistent ischæmia of the whole or a part of the brain, of a nature to induce the symptoms observed."

These were simple deductions from clinical observation. Since that epoch experimentation and observation have proven the reality of this opinion. In a series of experiments made under the most satisfactory scientific conditions, M.

Duret has permitted us to respond to this debated question, explaining the mechanism of concussion, and creating and demonstrating in a general way the pathological physiology of cerebral traumatisms.

Seeking the causes and mechanism of cerebral concussion induced by sudden injections into the interior of the cranium, M. Duret succeeded in reproducing the clinical forms of concusssion. Considering that the slowing up of the respiration and pulse, and the abolition of intellectual phenomena, are the most marked symptoms, and reflecting, on the other hand, that, according to the most recent physiological researches, the bulb is the centre of cardiac and pulmonary life, that it contains the fibres which place the intellectual centres in relation with exterior objects, M. Duret was led to seek for the lesions of concussion in this portion of the encephalon.

In order to exaggerate the shock on the cerebral hemispheres, and, consequently, the lesions it determines, he injected suddenly, through a small aperture, into the cranium of a vigorous dog, three ounces of liquid. The dog was killed immediately afterward, and at the autopsy was found an enormous dilatation of the aqueduct of Sylvius and of the central canal of the medulla, and besides this, the floor of the fourth ventricle had been torn (éclatement). On careful examination of this tear, M. Duret remarked that the parietes were turned outward, as if the tear was produced by a force acting from within outwardly, that is, from the interior of the ventricle toward the exterior; and he thence concluded that, through the considerable pressure suddenly brought about on the surface of the cerebral hemispheres, the cerebro-spinal fluid contained in the lateral ventricles had been suddenly expelled through the aqueduct of Sylvius, which was dilated and torn, into the fourth ventricle, which being thus over distended and presenting but a small external orifice, was suddenly split.

In order to prove that this lesion was really due to the cerebro-spinal liquid driven back by the experimental traumatism, and to prevent the objection that the lesion was produced by the injected liquid, M. Duret repeated the same experiment with a colored liquid susceptible of coagulation; "the same lesions were reproduced."

But it is yet necessary to demonstrate that this sudden driving back of the cerebro-spinal fluid, produced by the injection of a coagulable liquid on the surface of a hemisphere, exists really in traumatisms which affect the cranium.

The experiments of Brün and Felizet have abundantly proven that the cranium is in a great measure depressible and elastic; that there is produced a "cone of depression" at a percussed point, while at the opposite extremity of the axis of percussion there is produced a "cone of elevation (soulevement)."

We can, then, no longer deny the displacement and exaggerated tension of the cerebro-spinal fluid, since the blows and falls on the cranium flatten at one point the osseous envelop of the encephalon, which is itself incompressible. As we know, on the other hand, that the cerebro-spinal liquid has its source in the very fine membranes which surround the smaller arterioles of the brain substance, and that from thence it is spread over the periphery of the encephalon in the sub-arachnoid space, penetrating into the ventricles by the great fissure of the cerebrum, and descending thence toward the fourth ventricle and the central canal of the medulla by the aqueduct of Sylvius; since, as I say, these anatomical facts are known to us, it would seem natural to admit that the first effect of any augmentation of tension in this liquid would be to force it back toward its points of origin, and on the other hand toward the natural outlets. M. Duret has characterized this phenomena by an appropriate term, the cerebro-spinal shock (choc céphalo-rachidien).

If this shock has been of medium intensity, as happens in a certain number of clinical observations, the lesions will consist in a simple augmentation in the tension of the cerebro-spinal liquid and a momentary compression of the vessels of the brain substance. But if the shock is more violent, the liquid is of a sudden forced back into the lymphatic sheaths (gaines) and causes rupture of the smaller capillaries. These lesions of concussion are first evident at the part where the shock is most direct, at the "cone of depression," after that at the opposite extremity of the axis of percussion at the "cone of elevation," and at certain other parts of the surface of the brain. Again, as the shock is communicated to the entire mass of the cerebro-spinal liquid, it suddenly distends the sub-arachnoid space and its diverticuli, and the vessels there contained are ruptured. No matter where the shock commences, if it be violent, the liquid is driven back in the cavities of the ventricles in a certain manner; from the lateral ventricles it passes into the middle, and thence by the aqueduct of Sylvius into the fourth ventricle, which it distends and bursts open; this is why, in such cases, hemorrhagic effusions are found at the surface and in the substance of the bulb.

Since, then, the clinical symptoms of concussion are in exact correspondence with the lesions observed, there would seem to exist no possible objection to this doctrine of the mechanism of cerebral concussion.

There exists in the symptomatology of concussion a symptom rarely observed in practice, and which is never wanting when this condition is produced experimentally; it is a species of generalized tetanism of the voluntary and involuntary muscles, and particularly of those of the vascular system. This generalized contracture is evidently of reflex origin, and we have already demonstrated that the shock on the cranium is transmitted principally to the bulb, and to the entire encephalon; you have even been able to see the lesions of this organ.

You are also aware that there exists one part of the bulb, the restiform bodies, the irritation of which gives rise to tetanic effects not observed in other parts of the bulb. We can, then, safely conclude that this generalized tetanism is due to irritation of the restiform bodies.

This spasm, which affects particularly the muscles of the vascular system at the moment of the shock and for a few minutes afterward, is demonstrated by the elevation in arterial tension, which is most marked when the shock is violent (experiments of Duret and Franck). Duret has shown this specially for the vessels of the brain, by measuring the tension of the blood in the jugulars; at the moment of the shock it suddenly falls. If a final proof is wanting of this sudden cerebral anæmia, I would say that the movements of the brain, which are the result of arterial expansion, of the dilatation of the intracerebral vessels (Bech, Franck, Mosso, Salathé) are suddenly arrested at the moment of the shock (Duret).

Thus are explained the loss of cerebral functions, intellect, movement, sensibility, the sudden arrest of pulse and respiration, the troubles of calorification, etc.

In the second phase, there is general relaxation and complete resolution; to the spasm has succeeded paralysis of the entire vascular system, particularly of the cerebral vessels.

It is a law of general pathology, that any irritative lesion of the tissues determines first spasm and then paralysis. The flow of blood in the dilated capillary vessels about the nerve elements becomes slower, thence ensues the comatose state, and the dullness of intelligence, motion and sensibility, remarked in clinical observation.

The persistent troubles of intelligence, motion and sensibility are due to some material destruction of the parts, and are observed when the shock has been of great intensity. I do not wish in this lecture to speak of the third degree of inflammatory reaction, which will be considered when we treat of traumatic meningo-encephalitis.

We have seen, then, gentlemen, that the diverse troubles, variable as regards their intensity and duration, observed in cerebral concussion, can all be explained by the lesions determined by the sudden displacements and consequent changes in pressure in the cerebro-spinal fluid.

These lesions are, 1st, a simple augmentation in tension of the cerebro-spinal fluid, which induces momentary cerebral anæmia, or ruptures of the capillaries of the brain and pia mater, or, 2d, ruptures of the brain substance.

Every traumatism affecting the cranium has a more or less serious effect on the bulb, by the intermediary of the cerebro-spinal fluid.

We can now, then, complete the definition of concussion given at the commencement of this lecture. The designation concussion is given to a collection of nervous troubles of very variable duration and intensity, due to the reaction on the cerebral circulation and brain substance, brought about by the modifications in intensity and displacements of the cerebro-spinal fluids.

Communications.

PHYSICAL ASPECTS OF INFANTILE UNFOLDMENT.

BY THOMAS S. SOZINSKEY, M.D., PH.D.,
Of Philadelphia.

The nature of the young, but especially of the very young, is a branch of physiology which deserves much attention, far more, doubtless, than it receives. However this may be, it is certain that without a proper understanding of it, infantile welfare cannot be promoted, nor infantile diseases treated naturally and successfully.

It is extremely probable that many physicians, like people generally, know less than they suppose, about children. The manifold aspects of a child, physical and mental, constitute an extensive and complex branch of study. A child is indeed a difficult subject to fathom. How does it unfold physically? How does it unfold mentally? At what rate should it unfold physically? At what rate should it unfold mentally? What are the conditions suitable for its proper physical unfoldment? What are the conditions suitable for its proper mental unfoldment? How many, or perhaps I should say who, can answer these questions?

To some aspects of the physical unfoldment of infants I invite the attention of the reader in the remarks which succeed. What I shall say will have for a basis items of a record of observations made recently on a male child, during its first year, who was healthy and of about average size at birth, and who was cared for in all respects as hygienically, perhaps, as it is possible for a child to be. Of the observations, I may remark that, altogether, they may be taken as reasonably accurate. They were noted down week after week, as made. The peculiar relation of the observer to the child on whom they were made did not, I feel sure, tend to render them inaccurate.

It is proper to state, to begin with, that the child—an only one—is of healthy parentage, and of Anglo-saxon ancestry, free from constitutional diseases, and on the father's side, at least, extremely long lived; and that his parents are each in the prime of life, and each of about medium size, the mother being somewhat thin and the father somewhat stout. So much by way of pedigree for the child—a matter of great significance.

Now it may seem incredible, but it is nevertheless a fact, that in all the voluminous records of science, medical and otherwise, there is not, so far as I know, a complete record of the increase in weight and height, even from month to month, of a child that was healthy and well developed at birth and cared for hygienically in all respects, from day to day. This is almost equivalent to saying that there is no standard by which parents or the physician can judge of children, whether or not they are growing properly. I am aware that there are some records of features of the unfoldment of children, particularly as met with in institutions; but I believe every one will agree with me, when I say that the record of the unfoldment of such children is not a record of the unfoldment of children under proper conditions. A normal, or typical unfoldment of a child must be sought for elsewhere. If one is taken as a criterion, or standard, it should be one that was sound at the start, and that has been managed hygienically all along.

The efforts which have been made to delineate numerically the physical unfoldment of infants can be easily recounted. M. Bouchut made an approximate estimate of it, which he recorded in 1874, in the *Gazette des Hôpital*, No. 78. Dr. Hæhner made a record of the height of a healthy child of his at different periods during the first year, which may be found in the number of the *American Journal of Obstetrics*, for October, 1880. This is the only record of the increase of height, from time to time, with which I am acquainted, and it is not presented in a very practical shape. Dr. Etienne Evetsky, published in the New York *Medical Journal*, for February, 1881, an elaborate article on the results of an extended series of observations on the increase in weight, from week to week, of a large number of children during their first year, in the New York Infant Asylum. This is a valuable production, but I think that the author would hardly regard his figures as a standard by which to judge of the growth of healthy children hygienically reared. These articles embody all the precise information there is, or rather, that I am acquainted with, in regard to the increase in weight and height from time to time during the first year of life.

The vulgar belief that if a child is weighed or measured it will not live long, may account, in some measure, for the remarkable absence of records of the physical unfoldment of children. It would be well for every one's mind to be disabused of this strange superstition. The only ground for it, that I can imagine, is, that few or no observations of the kind have been made on any but sickly children—the sickliness prompting this attention. It would be wise to weigh all children every week or two, during at least the first year; for in this way only can it be determined precisely whether they are thriving evenly and sufficiently. In the light of such observations, faults in the conditions of existence of children can be discovered, and to some extent the presence of disease detected. For when an infant does not increase in weight at a due rate, it is a sure sign that there is something amiss. And having notice that something is amiss, a careful search will generally reveal what it is, and an intelligent effort will mostly remove it.

The following table gives the weight (including clothing) and height (or length, if any one prefers the word) of the child referred to, with approximate exactness, at birth, and at the end of each month of its first year:—

Age.	*Weight.*	*Height.*
At Birth	8 lbs.	19 inches
1 month	11 "	20½ "
2 "	14 "	22 "
3 "	16½ "	23¼ "
4 "	17¾ "	24½ "
5 "	18¾ "	25 "
6 "	20 "	26 "
7 "	21 "	26¾ "
8 "	22 "	27½ "
9 "	22¾ "	28 "
10 "	23¾ "	28¾ "
11 "	24¼ "	29½ "
12 "	25 "	30 "

It will be observed that at birth the child was eight pounds in weight and nineteen inches in height. This is no more, in either respect, than most male children are; it is probably not above the average of the healthy. Girls are somewhat less in both respects.

At three months the child's weight was sixteen and one-half pounds, which is over twice the original weight. This is the increase which a fairly developed child is usually said to make in the first six months, and not a few fail to exceed it within a year. Here the weight was over three times as much at eleven months as what it was at birth. Children that are very heavy at birth, say twelve pounds, rarely treble their weight within their first year; indeed, they generally do not do much more than double it.

The rate of increase in weight and height of the child was greatest during the first three months. For over three months there was a daily gain of over an ounce. The rate of increase during the fourth month was about two-thirds of an ounce daily. During the fifth month it was less, the falling off being produced, possibly, to some extent, by the cutting of two pairs of incisor teeth. The increase during the sixth month was nearly as great as in the fourth. During the seventh and eighth months it was somewhat over half an ounce daily. Warm weather may have had something to do in keeping it down during the seventh month. During the ninth and tenth months it was about two-fifths of an ounce daily; and during the eleventh and twelfth months somewhat less than two-fifths.

According to M. Bouchut, a child should gain 6.63 ounces weekly during the first month, and each month subsequently .44 ounces less than this per week till the end of the year, the increase then being 1.76 ounces weekly. Such an even decline in the increase is not met with probably in any case. However, according to this rule, a child weighing eight pounds at birth would weigh at the end of three months about thirteen pounds; at the end of six months about seventeen pounds; at the end of nine months about twenty pounds; and at the end of twelve months about twenty-one and a half pounds.

An examination of the table will show that there was an increase in both weight and height every month. Such, indeed, was the case week after week, without exception, I believe.

The proportion existing between the weight and height is deserving of very careful study, for, from the fact that some children are naturally of larger growth than others, the relations between the age and weight is a sufficiently poor standard by which to judge of the condition of children at any time. The figures given indicate that in the child's case there was an increase of about an inch in height for every increase of a pound in weight, except during the first three months, when it was less. The increase in height was possibly greater than it is in the majority of children. The average height of healthy children at the end of the first year has been given approximately as twenty-six inches; but this is considerably too low, I believe. Dr. Hæhner's child was almost thirty inches.

An English physician, Dr. Percy Boulton, in an article on observations made by him, read, two years ago, before the Harveian Society, and which has attracted wide attention, lays great stress on the importance of observing the proportion between the height and weight of children. He states that no difference what the rate of increase in height in different cases may be, "weight for height should be in each case identically the same." This rule possibly applies in children under three years of age; but Dr. Boulton's conclusions were based on observations made on children three years and upward. The Doctor found that "between three and four feet the increase in weight should be two pounds per inch, and between four and five feet two and a half pounds per inch." He states that a healthy, well-developed child is about three feet two inches in height and forty pounds in weight when three years of age. It would seem that the increase in weight per inch is much less during the first year than subsequently.

It may not be amiss to say, in this connection, that it should be borne in mind that the character of all children's tissues is not alike. Some have an excessive proportion of fat. Such children are flabby and inactive. The child whose measurements are given was not markedly fat at any time, and he was extremely active and strong all along. He received more exercise, probably, than most babies.

I will now give, as a matter of interest, a statement of the weekly increase in weight among the children in the New York Infant Asylum, as determined by the series of observations made under the supervision of Dr. Evetsky. The Doctor found that the average weight at birth was 7.176 pounds; that the average weekly increase during the first month was 2.53 ounces in spite of an actual decline of 1.08 ounces during the first week; that during the second it was 5.79; that during the third it was 5.12; that during the fourth it was 4.69; that during the

fifth it was 4.26; that during the sixth it was 3.39; that during the seventh it was 1.91; that during the eighth it was 3.46; that during the ninth it was 1.70; that during the tenth it was 1.69; that during the eleventh it was 2.63; and that during the twelfth it was 3.04.

Commenting on the result of his observations Dr. Evetsky says, "It will be seen that the child loses during the first week; then the growth rapidly increases, reaching its maximum during the seventh week. During the third, fourth, fifth, sixth and seventh months its energy declines, gradually at first, and more rapidly during the last two months, with the exception of the twenty-fifth and twenty-ninth weeks, when the growth is more active, reaching the lowest point during the twenty-eighth, twenty-ninth and thirtieth weeks. In the course of the following seven weeks (the eighth and ninth months), the growth is again more active, but it declines from the thirty-eighth to the forty-first week. From the forty-second week to the forty-fifth the child grows again with more vigor, which remains almost the same up to the end of the first year, with the exception of the forty-sixth, forty-seventh and forty-eighth weeks, when it is somewhat depressed."

In explanation of the manner of growth observed by him, Dr. Evetsky says: "The study of the growth of children during the first year leads to the following conclusions: Early childhood is composed of a number of distinct periods, of which the first is the *transient* (transition?) period, when the child's nutrition undergoes a change from the normal intra-uterine to the normal extra-uterine type. The pathology of this period rests upon the inadequacy of the feeble and imperfect efforts of assimilation to meet the requirements of the energetic nutritive processes. The second period is that of *normal extra-uterine nutrition*. After this there is a succession of three *dentition* and *inter-dentition* periods. The pathology of dentition rests upon the irritating influence of teething being transmitted to the nerve centres, producing certain disorders in the general and local nutrition and leading to a disposition to disease, or constituting the actual morbid processes. During the inter-dentition periods the child's health returns to the normal state. The growth of the child is not a process of itself, neither is it governed by its own laws, but is a faithful and correct representation of the child's general well-being. Consequently, its great clinical importance should be recognized. As information derived from weighing the child relates mainly to the state of the nutritive processes, while the linear measurements give us information concerning the energy of cellular life, both methods should be used concurrently in the study of this branch of pædiatric physiology."

Dr. Evetsky's remarks in respect to the effect of dentition on growth are, perhaps, much too emphatic; still, even in healthy children under hygienic influences the process has considerable effect, as a rule. In very many children met with in practice, the cutting of the teeth has undoubtedly a decidedly disturbing effect on the general health.

A few special features of the child's physical unfoldment will now be spoken of briefly.

Toward the end of the third month the child could readily and firmly hold in his hand any object placed therein. Two weeks later he began to put objects other than his fingers in his mouth. At five months he could easily reach out his hand and take hold of objects. Midway between the third and fourth month he could turn his head to observe objects. On the day he was six months old, it is stated of him in the record, that he "is able to sit up unsupported"—an ability which is commonly said to be acquired some time in the third quarter. Ten days before he was eight months old he could stand up cleverly when he had any point of support to cling to. At eight months he could crawl easily from point to point—an exercise in which he was allowed to indulge freely. A few days before he was ten months old he could stand alone, and a month later made slight attempts to walk, but walking was not fairly begun until he was a year old. If he had not been an expert creeper it is likely he would have walked sooner, for a good creeper is very sure to be disinclined to resort to a slower mode of locomotion. Many children walk before they have completed their first year.

When the child was four and a half months old one of the two middle incisor teeth of the lower jaw made its appearance. This is early, but not remarkably so for a child whose bony system is well developed. The old assertion, retailed so confidently in the books, that "dentition commences about the seventh month," to use the words of Paulus Ægeneta, does not hold good in the majority of cases. It not infrequently begins as early as the fourth, and sometimes as late as the tenth month. Another notion which does not hold good in a large proportion of cases is that the teeth come in pairs, the upper ones first. However, in this child's case the whole eight incisors were present when he was eight and a half months old. While they were coming through he seemingly suffered but little. In

some cases the lateral incisors are not present until the sixteenth month, or even later. It was only the other day that I had occasion to lance one in the lower jaw of a girl over sixteen months, in whom, by the way, the four small molars, two in either jaw, had been present for over a month. The cutting of the child's upper double teeth began when he was just eleven months, which is a year earlier than it is in not a few children. It troubled him somewhat; he was slightly feverish and restless, and a little inclined to have catarrh, with some disturbance of the alimentary apparatus. At the end of his twelfth month a molar on either side of the lower jaw were just appearing.

An entry in the record, made when the child was one year old, reads as follows: "So far he has not been affected with any disease whatever." It might be said that he did not suffer once from even a decided cold, colic, skin eruption, or chafing. It is a common idea, in the nursery at least, that every infant may be expected to have repeated attacks of colic. This is a mistake; no child who is free from disease at birth should ever suffer from colic. When a child is so affected, it is, as a rule, palpable proof that the nourishment it is receiving is not good, or that it is overfed, or that there is something else at fault in its case. It is not too much to say that if a child free from hereditary disease suffers habitually from colic, it may be reasonably assumed that its attendants are not performing their duty intelligently and faithfully.

Another entry made at the end of the child's first year reads as follows: "He has not cried five minutes continuously since he was born." As a matter of fact he never cried half that time continuously. Yet he was always very spirited; his abstinence from crying was not due to natural apathy. Really no child that is well and wisely cared for is ever inclined to cry. Pain and irritability of temper are the main causes of the crying of children; and these will not be present, as a rule, if the management is of the right sort.

Here is still another interesting item of the record inserted at the end of the year: "For many months the child has had, as a rule, but one alvine evacuation daily. In his early months there were seldom more than two, and frequently only one." I am disposed to believe that this is as it should be; in spite of statements enough to the contrary, it is not natural for an infant to have three or four evacuations daily. It nearly all depends on the quality and amount of its nourishment. The child's mother led a perfectly regular life and lived on simple fare, the main item of which was milk; and she fed him, for the most part, at set periods. Up until the end of the first year his nourishment was derived from the breast exclusively.

A few additional facts in regard to the child's condition at the end of his first year may be given. The circumference of his head was 18¾ inches, of his neck 8, of his chest (without clothing) 19, of his forearm 6, and of his leg 7¼. His pulse at various hours, on many different days, when awake, was at or near 140 per minute. When asleep it was about ten beats less. In the books it is said that the pulse of a child during the first year is from 115 to 130 per minute.

Besides the influences referred to, or hinted at, as bearing on the unfoldment of children, there is one about which I cannot refrain from saying a few words before concluding. The influence to which I refer is that of the seasons. Unless an infant is very wisely cared for, both the heat of summer and the cold of winter are apt to have a retarding effect on the growth. If the heat of summer, however, does not produce prostration of any account, it is then that growth progresses most rapidly, as one might expect. The child the facts of whose physical unfoldment I have given was born on the 29th of January, 1881. The heat of summer did not apparently have any prostrating effect on him at any time.

PLACENTA PRÆVIA.

BY J. D. STRAWBRIDGE, M.D.,
Of Danville, Pa.

Early in the summer of 1851 a woman ran crying from a house which I at that moment happened to be passing, and I turned to see what was the matter, when, recognizing me, she exclaimed, "Oh! Doctor, come up quick, Mrs. L. is dying." Following up stairs as rapidly as possible, I found the patient lying on her left side, her back toward me, near the edge of the bed, through which blood flowed in a stream to the floor. I inquired, "Is she in labor?" and the reply, "I guess so," was scarcely given, when a torrent of blood poured over the side of the bed, flooding for some distance the uncarpeted floor. A low, stifled moan, gasping breathing, ineffectual efforts at vomiting, the blanched face, and almost complete unconsciousness, showed clearly that there was no time to lose. I instantly threw off my coat, bared my right arm, and introducing my hand into the vagina, through a relaxed and easily dilated vulva, passed my finger rapidly around inside the os, which I found relaxed and dilated to nearly two inches in diameter, and through which a mass of placenta

presented. I searched for some point of detachment by which to reach the membranes, but found the placenta firmly adherent all around to within little more than half an inch of the edge of the os. The fœtus could be felt through the placenta, but moving so freely in the abundant waters as to evade the touch, and prevent the presentation being ascertained. Finding a slight break in the presenting placental mass, directly across its centre, without hesitation or a moment's delay, I thrust my hand in this opening, through the placenta into the uterus, giving exit to a large flow of waters; grasping the vertex, which came at once into my hand, I gave it a turn to the left, then placing my finger in front of the right shoulder, while the waters were still discharging, rotated the body on its axis until the feet were brought nearly to the front, where they were easily reached, the child turned and delivered, within ten minutes from the time I entered the room. The secundines, inverted through the torn placenta, followed immediately after the head. The child, which was in the beginning of its seventh month, showed no signs of life, and no effort was made to resuscitate it. As soon as it could be laid to one side, I administered to the mother (who had partially recovered consciousness), a teaspoonful of tincture of camphor in water (the only stimulant at hand), and a few minutes later, 30 grains of powdered ergot in infusion. There was no further hemorrhage, and the patient, although in a state of extreme exhaustion, recovered rapidly, without a bad symptom, and within the month was able to look after the affairs of her household. The placenta proved to have been placed centrally over the internal os, and was torn through, close to the insertion of the cord.

As soon after as my patient could be safely left I called upon Dr. Wm. H. Magill for advice in this case, and learned that he had had an almost similar experience with the same patient about one year before. Mrs. L., being then in her first pregnancy, and, as she supposed, in her sixth month, was suddenly taken with a large flow of blood while standing at work; she was put to bed as soon as possible, and her physician, Dr. W. R. Gearhart, called; finding no signs of labor, the vagina was tamponed and the Doctor left to attend to other calls; returning a few hours later, he found the patient faint and weak, and, notwithstanding the presence of the tampons, the hemorrhage was again becoming dangerous. Alarmed at this condition, he sent in haste for Dr. Magill, who at once removed the tampons; finding the os sufficiently dilated, he detached the placenta at the side, ruptured the membranes with his fingers, and rapidly effected version and delivery by the feet; although no delay occurred in delivery, and but little force was required, the child showed no signs of life. A little less than one year from my first attendance I was again called in haste to Mrs. L., and found her in bed, having been taking suddenly a few minutes before, with profuse hemorrhage. She was then near the end of her sixth month of pregnancy, and, certain that I had again a placenta prævia to deal with, I had in my pocket a package containing three drachms of powdered ergot, which I handed to one of the attendants, with directions to put it in half a teacupful of boiling water, and return with it immediately. While preparing for an examination, a sudden gush of blood, which filled the bed and clothing about the patient, warned me that there was no time for delay, or the catastrophe so narrowly averted on the former occasion might be realized on this. I found complete dilatation of the soft parts, some small coagula still in the vagina, and blood flowing in a continuous stream from the partially dilated os, through which a mass of placenta presented; a partial detachment at one side, where a forming bag of waters could be felt, enabled me to rupture the membranes at once and pass my hand up into the uterus, as the waters flowed rapidly away, and the head began to come down. I found the pressure of my hand had almost completely arrested the hemorrhage. The attendant was directed to administer one third of the infusion of ergot, and I determined to await results. At the end of fifteen minutes a second portion was given, and in about fifteen minutes more uterine contractions began, and soon the head was pressing down firmly into my hand, which I began slowly to withdraw, taking care not to relax pressure on the placenta until it was compressed firmly by the head. The labor progressed rapidly, and within an hour from my arrival a dead child was delivered. The patient was but little more exhausted than in an ordinary labor, and was able to be up on the tenth day. In December of the same year I learned from Mrs. L. that she was again pregnant, and dreaded a recurrence of her former trouble. I charged her to go to bed and send at once for a physician on the appearance of the slightest hemorrhage. Accordingly, in the latter part of January, 1853, I was called, and found her in bed, having had a slight show, with some fugitive pains about the back and abdomen. A digital examination showed no signs of labor. She believed herself then at the middle of her seventh month. I enjoined rest in

bed, cold drinks, and prescribed a few doses of acetate of lead and opium; in a few hours the hemorrhage ceased, and the next day, in spite of my injunction, she was again about the house. These attacks recurred at intervals of about a week, increasing in quantity and duration of flow with each return, for which, after the first attack, I prescribed, to be alternated with the acetate of lead and opium, five grains of powdered ergot every four hours. About the middle of March I was called in haste, and found her in bed, with regular labor pains, accompanied with free hemorrhage; the os dilated to the size of a silver dollar, through which the edge of the placenta protruded. Pressing this to one side, I ruptured the membranes; the pains increased rapidly, and soon the vertex presented. With the pressure of the head on the placenta the hemorrhage soon ceased. I felt that I could trust to the natural powers for a satisfactory result. After an easy labor of about two hours, my patient was the mother of a fine, healthy boy, now a successful business man in the State of Ohio and the father of several healthy children. The family were preparing to leave Danville, and soon after went to their new home in Ohio.

While visiting a patient a few weeks since, I was introduced to Mrs. L., a fine, matronly-looking widow lady, of about fifty years; to my great surprise I found she was my former patient, whom I had not seen or even heard of for over twenty-seven years. At this meeting all the circumstances here related were recalled and discussed. I learned that after leaving Danville she had given birth to several children, without any complication whatever, but none of whom lived to grow up. She promised to see me again and furnish me more accurate data of her case, my own records having been lost while absent from home during the war; but professional duties called me from home, and Mrs. L. left Danville without seeing me again. This, with but one exception, where the condition was but partial, is the only patient in my own practice in whom I have met with "placenta prævia," although, between my last attendance on Mrs. L., in the spring of 1853 and the fall of 1860, when I temporarily retired from practice, I attended in more than 1700 cases of labor.

—An act enforcing compulsory vaccination has been passed by the Parliament of Tasmania, and assented to by the Governor. 12,000 persons in South Australia have been vaccinated during the last two months. The registered number of successful vaccinations on children under 14 years of age, in New Zealand, during the last four years, was 48,253.

Hospital Reports.

UNIVERSITY HOSPITAL.

CLINIC OF LOUIS A DUHRING, M.D.,

Professor of Dermatology.

Reported by Fred A. Taylor, M.D.

Case 1.—Erythema Multiforma.

There comes before us first a German woman, about fifty-five years old, with an eruption on her hands and arms, confined chiefly to the extensor surfaces. The disease is characterized by variously sized, ill-defined, erythematous, distinctly elevated patches, made up of split-pea sized, modified papules, tending to run together. The modifications of these papules play an important part in the picture of the disease, since they constitute it a case of erythema multiforma. It is a characteristic case of the papular variety of this disease. As the name indicates, the case exhibits a variety of lesions, which taken together, make up the definite disease. Some of the papules making up the patches are simple, distinct, and of a bright reddish hue; most of them, however, are papulo vesicles; *i. e.*, having begun as a papule and attained the size of a split pea, or larger, a vesicle has developed in the centre, which is of various size relative to the papule, and of a violaceous color, which gives a variegated appearance to the lesions that is quite characteristic of the disease. Passing your finger over the lesions you notice the marked elevation, much more distinct to the touch than to the sight. On the right arm the disease is less developed than on the left. You have observed how distinctly the disease is here confined to the backs of the forearms, hands and fingers. This is its usual seat. An eruption coming out rapidly, and confined to these regions, you may justly suspect to be erythema multiforma.

The disease is not a common one with us, but appears most frequently in the spring and autumn. As a rule, the general health is not at all or but slightly affected, and the subjective symptoms are not marked; the disease being as a rule accompanied with but little itching, though patients sometimes complain of a sense of heat or burning. It makes its appearance rapidly, and usually runs its course in from ten days to three or four weeks, disappearing of itself; it consequently is not often brought to the notice of the specialist. The disease looks more formidable than it really is. It has a tendency to relapse, however, and a person who has once had it is liable to a second attack. Both children and adults of either sex are liable to it; it is more common, however, in women between the ages of fifteen and thirty.

Treatment is, as a rule, of little avail. No internal or external remedies materially affect it. In markedly vesicular cases the fluid extract of grindelia robusta sometimes exerts an influence over the vesiculation, but there is no indication for its use in the present case. The disease will get well of itself, the lesions changing in color, some becoming yellowish and others bluish as they pass away.

Case 2.—Acne Vulgaris (pustulosa).

Our next case is that of a girl, seventeen years of age, in manifestly low condition of health, who exhibits an unusually marked case of acne of the face, back and chest. She has had the disease eight years; its first appearance being slight, she says, but being as bad as it now is for four or five years. It is characterized by large papules and pustules, covering nearly every portion of the face. You can hardly discover a single healthy square line on its surface. The pustules are suppurating freely so that the face is dotted over with yellowish points. On the back and shoulder-blades the eruption is scarcely less severe. Here you find papules in every stage of development; small and reddish in their commencement, increasing in size as they become older, some of them finally tubercular or suppurating; and scattered about among them are violaceous and muddy-colored spots showing where former papules have existed. The front of the chest over the sternum and upper ribs is quite thickly studded with similar lesions.

Inquiring into her history we learn that the girl has suffered from epilepsy in a mild form since she was three years of age. She has been under treatment for this latter disease many years, taking bromide of potassium most of the time. Now, as the continued administration of this drug often provokes an eruption of acute acne, we are led to suspect this to be the exciting cause in the present case. On further inquiry, however, we learn that the acne had been established before she began to take the bromide. Moreover, judging from the prescription she shows us, the amount she has been in the habit of taking is not sufficient to have produced the acne. It is, then, an idiopathic case of acne vulgaris, probably aggravated by the use of the bromide of potassium.

It will require six months, or longer, to effect a cure. Her low, ill-nourished condition indicates a constitutional treatment. We will prescribe a preparation of iron and quinia, to be taken three times a day. We will also give her, if she continues to take the bromide of potassium, two or three minims of Fowler's solution of arsenic, daily. This will be to correct the influence of the bromide on the acne. If she does not take the bromide, the arsenic will not be given. Locally, the diseased parts must be bathed in hot water, by means of a sponge, fifteen minutes, every night. The pustules must be opened, both before and after bathing, either with a needle or a sharp-pointed knife. After the bath, an ointment of precipitated sulphur, a drachm to the ounce of cosmoline, must be thoroughly applied. This treatment will be continued two weeks. At the end of that time the condition will be very much improved. The strength of the ointment will then be increased to two drachms of the sulphur to the ounce. After continuing with this three or four weeks longer, the ointment will be suspended, and, perhaps, the hot bath also. We will then, possibly, use the following lotion:—

℞. Zinci sulphatis,
Potassii sulphureti, āā ℥j
Alcoholis, f℥ss
Aquæ, f℥vss. M.

Sig.—To be dabbed on every night and allowed to dry. Shake before using.

Her bowels must be kept open, if necessary, by a saline laxative, taken before breakfast. The tonics will be employed for some time, and, perhaps, later in the treatment, arsenic internally.

Case 3.—Tinea Tonsurans.

The next patient is a little boy, about six years old, with light hair, who has a disease of the scalp, exhibiting extensive characteristic patches of tinea tonsurans. It is a case, you will remember, that was before the clinic about a month ago, and I have not seen it since. At that time the treatment advised was thorough depilation of the diseased surface, and the application of sapo viridis followed by sulphurous acid. The treatment has not, I venture to say, been properly carried out, and there is, consequently, not much improvement. The scalp over the vertex and back part of the head is devoid of healthy hair, but is studded with the short stumps of hairs which have been eaten away by the vegetable parasite which characterizes the disease. These short hairs are loaded with the fungus. Here and there is an ill-defined circular patch, where the skin is more completely denuded. The skin is dry, scurfy, and exhibits the characteristic "goose-flesh" appearance. The peculiar light yellow color of his hair is due to the bleaching effect of the sulphurous acid which has been applied.

To effect a cure in a severe case of tinea tonsurans is no simple matter. It may require from three months to a year of attentive treatment. To be properly treated it must be seen every day or every other day, and half an hour be devoted to the careful removal of hair from the diseased surface; then the local applications must be thoroughly made. Even under such care as this, the disease may resist treatment for months. The treatment of tinea tonsurans does not generally gain much credit for the physician. It is often so obstinate a disease, and it so rarely receives the constant attention it demands, that frequently it lingers indefinitely.

By proper attention, however, any such case may be cured. In the one before us the scalp is too dry for the use of a lotion, and we will, therefore, discontinue the sulphurous acid and substitute the oleate of mercury with a strength of five per cent. Later, the strength of the ointment will be increased to ten per cent., constantly guarding against salivation. Before the applications of the ointment the surface will be thoroughly washed and depilated. We will see that our patient appears before us oftener.

Case 4.—Excoriated Papular Eczema.

A woman, forty-five or fifty years of age, hard-working and spare, presents herself with a disease on the front of the leg extending from the ankle to the knee. It constitutes one large ovalish patch, irregular in outline, covering the entire front of the leg and showing an erythematous surface scattered over with numerous distinct excoriated papules. It is a case of excoriated papular eczema. The whole surface has been severely scratched, and the excoriations are very marked. The disease evidently causes her great suffering. The itching, she says, is in-

tolerable, and prevents her sleeping. She has had the disease three years, but of late it has been spreading. It has an acute appearance, the lesions being bright red, and evidently recent.

It is a case where strong remedies are needed. There are two or three lotions that may be used. Carbolic acid and thymol both act happily in such cases. The alkaline tar lotion also might be used, according to the following formula:—

℞. Picis liquidæ, ʒij
Potassæ, ʒj
Aquæ, fʒv. M.

Sig.—Dilute a teaspoonful into two or four ounces of water, and use freely as a lotion.

In this case, however, we will first employ the carbolic acid, prepared as follows:—

℞. Acidi carbolici, fʒij
Glycerinæ, fʒss
Alcoholis, fʒij
Aquæ, ad Oj. M.

This will be applied freely, three times a day, for ten minutes at a time. The application may cause smarting, but its use should be persisted in for three or four days. At the end of this time the more acute symptoms will have subsided, and we will substitute the lotion by an ointment of white precipitate or calomel, thirty grains to the ounce of cosmoline and oxide of zinc ointment. The use of the lotion may, perhaps, be repeated from time to time. It will, probably, require several months to effect a complete cure.

Case 5.—Chancroid.

The next case is that of a negro about twenty-five years old, who has, he says, a skin disease on the penis. There is an ulcer of the size of a large split pea, occupying the inner surface of the prepuce and its reflection on to the glans penis. There are also two or three small superficial ones, and a marked excoriation on the glans itself. The large ulcer has an elevated border, and no induration. It made its appearance as a small lesion, four or five days ago, which, he states, was about six days after intercourse. This is plainly a chancroid. You will find it stated that chancroids may appear five, seven, or more days, after infection. In my experience the sores usually make their appearance much earlier than this. I recall an exceptional case, seen recently in a physician, where an excoriation the size of a small split pea was developed within twelve hours after the infecting intercourse.

The treatment in this case will consist in his maintaining absolute cleanliness, by washing the parts three or four times a day, and then dusting with a small amount of iodoform powder. If the odor of the powder is too offensive, it may be made into an ointment with balsam of Peru and vaseline:—

℞. Iodoformi,
Balsami peruvianæ, āā gr. xv
Unguenti petrolei, gr. xxx. M.

Sig.—To be applied two or three times daily.

The ulcer will probably soon heal under this treatment.

Case 6.—Purpura Simplex.

This man, about forty-five years of age, comes before us to show the result of the treatment we prescribed a week or two ago, for purpura simplex of the thigh and legs. You will remember that when he was before us last, the thighs and legs were everywhere thickly mottled with small hemorrhagic spots of a reddish and purplish hue. To-day he is much better. The lesions have faded to a light brownish-red color, and in some places have almost entirely disappeared. His treatment was a drachm of the fluid extract of ergot, three times a day. The remedy will be continued.

Quebracho.

In *El Genio Médico-Quirurgico*, Madrid, January 7th, 1882, Dr. Fr. Simon, of Nieto, publishes an interesting report on the above substance, from which we extract as follows:—

Quebracho is the bark of a tree (*aspidosperma quebracho blanco*) which grows in South America; in color it resembles calisaya bark, and has a hot, bitter, and intensely disagreeable, acrid taste. Penzoldt first noticed its medicinal value; others, among whom Berthold, Krauth, Schütz, and Laquer, have also experimented with it. All the observations thus recorded agree with those made by Dr. Simon, and point to quebracho as a specific in dyspnœa, whether resulting from asthma, or chronic or acute affections of the respiratory or circulatory systems, or when due to emphysema and pulmonary catarrh.

Two methods of preparing quebracho have been recommended by Penzoldt: the one, a tincture (1 to 10), of which the dose is from forty-five minims to one drachm, daily; the other, an aqueous extract, which is obtained in the following way: 150 grains of pulverized quebracho are digested in three ounces of alcohol; they are then evaporated and dissolved in water; the solution is filtered and evaporated to dryness. This forms the dry extract, of which the dose is from 15 to 30 grains, daily; or it is dissolved in twenty times its weight of boiling water, and then constitutes the liquid extract, which Penzoldt prefers to any other form, not excluding *aspidospermine* (an alkaloid obtained by Frande); two to four teaspoonfuls of the liquid extract may be given daily.

Dr. Simon details six different cases in which he administered quebracho successfully, besides some interesting experiments made upon himself, and he recommends the two following formulæ:—

℞. Tincture of quebracho (1 to 10), ℥j
Water, f℥iiss
Syrup, f℥ss. M.
Sig.—A tablespoonful every four hours.

℞. Dry extract of quebracho, gr. xxx
Water, f℥iss
Syrup, f℥j. M.
Sig.—A teaspoonful every half hour, until relief is obtained.

He concludes his report with the following observations:—

1. Quebracho is a substance possessing the property of moderating respiratory movements; it acts, in truth, as the digitalis of the lungs.

2. It relieves dyspnœa, whether resulting from purely nervous disorders, or when due to anatomical alterations in the respiratory or circulatory apparatus.

3. Its action is immediate and its effects safe, at least, so far as observed.

4. Its effects on dyspnœa caused by circulatory troubles warrant the belief that it not only acts directly on the nervous system governing the respiratory movements, but that its influence extends over cardiac innervation.

5. Finally, it is believed that quebracho facilitates expectoration.

Addison's Disease.

From the London *Medical Times and Gazette* we learn that an interesting contribution to the pathology of Addison's disease was brought by Dr. Goodhart before the last meeting of the Pathological Society, and gave rise to a still more interesting discussion. The cases briefly consisted in atrophy or complete disappearance of the supra-renal capsules, associated with all the clinical features of Addison's disease in a marked degree. It would appear, therefore, that the changes in the capsules which Addison and all subsequent writers have considered essential to the disease may, after all, be only one of several conditions capable of giving rise to this group of symptoms. Many facts were brought forward in support of this opinion. Dr. Goodhart himself was of opinion that such cases as these strongly suggested the view that changes in the abdominal sympathetic were the real source of the symptoms—a view which was traversed by Dr. Pye-Smith, who, after pointing out that the adrenals were obsolete organs in adult life, the removal or destruction of which in animals produced no effect, warned his hearers against the acceptance of this neurotic theory, on the ground of its extremely simple and seductive nature. He supplemented this by pointing out that pigmentation of the skin was very common, and that there was neither pathological nor physiological analogy in support of melasma being due to nerve changes. Dr. Coupland was hardly prepared to accept Dr. Pye-Smith's views, and pointed out the striking analogy presented by the vomiting and pigmentation of pregnancy in support of disorder or implication of the abdominal sympathetic. He did not think that structural changes need necessarily be found in the nerve ganglia themselves, although he had met with one notable example, where fibrosis with atrophy of cells existed. He expressed his belief that the changes in the supra-renal capsules were of the nature of a localized tuberculosis, which might take place without any symptoms of Addison's disease. Dr. C. Creighton, in regard to the function of these bodies, referred to the researches which had shown that the blood issuing from the capsules gave chemical reactions different from those which were obtained from blood entering them, and argued that changes, such as atrophy, or caseation, which practically cut off the blood supply, might lead to such alteration in the blood as would bring on pigmentation, while cancerous changes, which increased the circulation through the organs, would have no such effect. Finally, Dr. Fowler referred to a case of lymphadenoma, in which the abdominal sympathetic was largely invaded, where the capsules were healthy, and in which all the symptoms of Addison's disease were present.

Fibrous Tumor of the Uterine Neck.

Paris *Médical*, January 21st, 1882, reports, that at a sitting of the "Académie de Médecine," M. Depaul exhibited a tumor which he had removed from a woman arrived at nearly her full term in pregnancy, and which not only rendered delivery impossible, but would have caused the death of both mother and child.

The patient, a woman 32 years old, was in her fourth pregnancy, the three others having terminated normally. Her general and local health were unimpaired. A few days prior to her admission into the lying-in hospital she felt something protruding from the lips of the vulva, and, according to her report, a midwife and a physician both declared it to be part of the placenta which had become detached. On examination, M. Depaul discovered protruding from the vulva a purple-red tumor, as large as the extremity of the hand. Its texture was firm, although supple and elastic, and it emitted a most fetid smell, due to contact with air and want of cleanliness, as there existed no trace of gangrene. The tumor so filled the vagina as to prevent the finger from reaching the orifice of the uterine neck. M. Depaul ordered a full bath and postponed further examination. The next day he found the patient in labor. The projecting portions of the tumor had increased to the size of two fists, and it pressed against the vulva in such a way that a finger even could not be introduced into the vagina. The waters had drained off, and the child was suffering; this was evident from the reduced heart beats. Immediate action was necessary. M. Depaul gradually drew the enormous mass from the vagina, and by careful examination made sure that its point of adherence was on the left side of the anterior lip of the neck. In drawing out the tumor part of this anterior lip had followed, and it became clearly visible that this was the seat of the fibrous mass. With the aid of a bistoury, M. Depaul severed

the pedicle of the tumor, and found that it measured between five and six centimeters. As is the case with fibrous uterine bodies, no hemorrhage followed.

This tumor was remarkable on account of its weight, which was fifty-six ounces, it being the largest that has thus far been observed.

After removing the tumor the child was delivered by means of a blunt hook applied on the hip fold, it being a breech presentation. The child was still alive, and both it and the mother are now in perfect health.

A histological examination of the tumor showed that it was composed of elements from the connective and smooth fibrous tissues. There were besides cavities containing sanguineous collections.

A New and Reliable Operation for the Cure of Webbed Fingers.

Arthur T. Norton, F.R.C.S., contributes the following to the *British Medical Journal*:—

C. K. was sent to me by Mr. Moore, of Chiswick. The boy, one of four children, was about four years of age, and had the three inner fingers of the left hand webbed together. No relative had suffered from the same deformity. The operation which I performed can be best explained, and, indeed, can only be understood, by referring to the diagram.

A tongue of integument was cut from between the knuckles, and another corresponding in shape, and position, and size, on the palmar surface. These tongues were then raised by dissection, and the webs cut through. The knife was then carried back so as to sever all the tissues as far back as the bases of the tongues, and a little superabundant tissue was removed. Next, the apices of the tongues were sewn together, and lint, dipped in cold water, applied. The flaps or tongues united by the first intention between the little and ring fingers, but one of the pair between the ring and middle fingers sloughed at its apex from its suture. The cause of the sloughing was incomplete section of the tissue between the fingers up to the base of the tongues, the result of which was too great tension, and consequently giving way, at the suture. However, even in this case, the tongues separated only a very short distance, and the interspace rapidly healed, so that there was no redevelopment of the web.

A drawing of the hand was taken after the operation, by which it will be seen that, in the case of the middle and third finger, a little more tissue might have been removed with advantage after the raising of the tongues, in order to bring the line of the natural web into proper position. The healing of the fingers progressed rapidly in the middle finger and on the outer side of the ring finger. Between the ring and little fingers the healing was not so rapid, because the web between these fingers was thick and narrow, so that, after its section, a larger surface was denuded.

The points to be considered in performing the operation are these: 1. The tongues should be cut thick, so that their vascular supply may be complete, and the chance of their sloughing reduced to a minimum. 2. They should be cut rather narrow, with judgment; otherwise, they are compressed laterally and bulge upward at the margins, instead of lying in adaptation to adjacent tissues. Such compression, of course, interferes with their circulation. 3. The tissue between the knuckles is to be cut back, or, if necessary, cut away, so that the apices of the tongues shall lie well in contact with each other without tension. 4. The tongues must be of sufficient length, so that there shall be no tension when the suture is applied; they had better be too long than too short. 5. The apices of the tongues are very small, so that a very small needle should be used to carry the suture. 6. In shaping the tongues the line of the natural web should be carefully observed. If the tongues

heal by first intention, no web can redevelop. There is no reason whatever why union by the first intention should not invariably take place if the above points are remembered while performing the operation, and thus one of the most troublesome and unsuccessful of operations is converted into one of the most simple and most certain of success.

Splenotomy Not a Justifiable Operation in Leucocythæmia?

Herbert Collier, M.R.C.S., contributes a lengthy paper on this subject to the London *Lancet*. From it we note that twenty years ago extirpation of the spleen for disease of that organ was

looked upon rather as a surgical experiment than a recognized operation; and of the four cases which had up to that time been put upon record, the first two were discredited by the majority of writers, and the other two, which had both proved fatal, were regarded as conclusive evidence of the hopelessness of the operation. The first case of splenotomy in England was performed by Mr. Spencer Wells, in 1865, for simple hypertrophy, and the result was sufficiently encouraging to inspire not a few surgeons with the hope that at no distant date removal of the spleen would become as recognized and valuable an operation as ovariotomy was at that time. Mr. Spencer Wells' example was followed by Mr. Bryant, in 1866, and again in 1867, and both patients sank almost immediately after the operation. An exhaustive statistical table of twenty-nine operations furnishes the following results. It was performed sixteen times for leucocythæmia and thirteen times for various other morbid conditions of the spleen. It appears that out of the thirteen cases in which leucocythæmia was absent, no less than eight recoveries are recorded, while out of the sixteen in which the latter disease was present, there is no instance in which the patient recovered even from the primary effects of the operation. Now, it must strike the most casual observer that the fatality in these latter cases is due to something outside the mere effects of the operation, which, in itself, appears to be less dangerous than one might reasonably be led to expect. And surely, few will deny, although many appear to forget, that this "something" is actually present in these cases, and readily explains the cause of surgeons losing at the rate of a hundred per cent. after splenotomy in leucocythæmia.

Dr. Gowers, writing in "Reynolds' System of Medicine," says:—

In leucocythæmia the tendency to hemorrhage is unquestionably greater than in most cases of simple splenic anæmia, and this constitutes a danger so great as to render the operation (splenotomy) scarcely justifiable in the advanced stages of the disease. Naturally, a risk of immediate death so great as is and must be involved in the operation is only consented to when the disease is advanced, and the œdema and dyspnœa in themselves indicative of the greatest source of risk—the profound blood change. We are yet, moreover, without any evidence as to whether the removal of the spleen would be attended with an improvement in the deficiency of the red globules, which constitutes the greatest source of danger.

Professor Mosler, writing on excision of the spleen as a remedy in leucocythæmia, thus concludes his remarks: "These facts lead us to the conclusion that neither in the early nor in the late stages of leucocythæmia is splenotomy justifiable; and, indeed, that operations even of the most trifling character are to be as far as possible avoided."

Summing up the lessons taught by his two cases, Mr. Bryant, writes: "We have thus learned two things from the cases related. First, that the enlargement of the spleen in leucocythæmia appears to be only a part of a general disease affecting the glandular system as a whole; and, second, that in splenotomy for such a disease there is a predisposition to hemorrhage with which surgery is incompetent to deal. It can neither be foreseen by any amount of care, nor coped with by any amount of skill. Under these circumstances there is no shirking the conclusion that the operation is physiologically unsound and surgically unsafe, and for leucocythæmia, should not be performed." To these remarks, coming as they do from one who has fully realized upon how slight a fabric the theory of splenotomy as a remedy for leucocythæmia is built, it will surely be unnecessary to add more. And, in conclusion, let me trust that the recorded facts, together with the condemnation of the operation by the high authorities I have quoted, will suffice to prevent the further repetition of this useless and deadly experiment.

Two Cases of Paroxysmal Hæmoglobinuria.

Dr. Robert Saundby reports the following instructive cases in the *Medical Times and Gazette:*

In the *Medical Times and Gazette*, for May 1, 1880, I described a remarkable and unique case of hemoglobinuria in a youth of sixteen, who presented the following peculiarities: He was of a peculiar yellow, anæmic complexion, the yellowness being more marked during his attacks; he had an enormous spleen, reaching down to the umbilicus; his blood presented the characters of slight anæmia; his urine *always* contained more or less hæmoglobin. I mentioned that it was hereditary, his father having had a similar enlarged spleen, and passed water of the same character; and that a sister was also a victim to this peculiar affection.

Recently I was called to see the sister for a trifling indisposition, when I ascertained the following facts: She presents no abnormal physical signs, especially no evidence of splenic enlargement; her complexion is slightly ochre-tinged, like the brother's; her urine always contains a trace of hæmoglobin without albumen. She is now sixteen, and had menstruated for a short time regularly, but this has stopped for the last six months. She appears in other respects a well grown, well developed, intelligent young girl.

The brother has exhibited symptoms of mental aberration which gave rise to so much difficulty that I certified him as insane, and he was for a short time in an asylum. He seems quite unable to settle to any occupation: his mind is full of the most extravagant schemes; he appears unable to realize his position in life, and systematically ignores the state of his health. He has several times run away from home, at one time getting as far as Belgium. There is no history of insanity in the family, but during the latter part of his father's illness he was very peculiar; he was at times violent to his wife, and he distressed her very much by confessing to her that he had been unfaithful—a statement which she took pains to investigate, and she assured me that she believed it was entirely unfounded.

At the end of 1880 I had a young gentleman sent to me by my friend, Mr. G. W. Tait, of Knowle, as a case of chronic Bright's disease. He had had persistent albuminuria since Janu-

ary, 1878, and had been seen by several physicians—among others by Dr. George Johnson—by all of whom he was regarded as a case of Bright's disease. He had spent the previous winter in Italy. His own account of himself was that he had had several attacks of hæmaturia without any dropsy; the first came on with a sore throat. On examining his urine it was clear, specific gravity 1.008, and contained a dense cloud of albumen, but no casts. There was no cardiac hypertrophy, nor evidence of polyuria; the pulse was hard. His general appearance was that of a fairly healthy, well-developed young man, and the constant absence of casts in the urine induced me to give a guarded but favorable opinion of his case. The idea of hæmoglobinuria was present to my mind, but had little to support it at that time. I saw him from time to time during that winter, but lost sight of him till last October, when I was sent for to see him at a country house where he was staying, and found him in bed, perspiring freely, in no pain; pulse 108; temperature 104.2° Fahr.; tongue furred; bowels confined; fauces slightly injected; no sickness or headache; no œdema; physical signs in thorax and abdomen negative. He told me that he had had a cold for a fortnight, and had felt "shivery" for the last few days, but had had no definite rigor. His urine was black, and contained hæmoglobin, albumen, granular matter, and hyaline casts. On the following day his temperature at the same hour (4.30 P.M.) was 105.2°, and the urine just passed showed, under the microscope, granular matter, hyaline and granular casts, and pigment, but no blood-corpuscles or oxalates. He was ill altogether about three weeks, but the urine began to get slowly lighter after four or five days. I tried him with chloride of ammonium for a day or two, but he disliked it, and it produced no effect, so I substituted two grains of quinine, three times a day, dissolved in hydrochloric acid, which, together with an occasional dose of Carlsbad salts, he took until he was convalescent.

This case is of interest on account of the persistence of albumen in the urine, a symptom which has been recorded in another case by Dr. Forest. He has had no relapse since, but I have strongly urged the desirability of his seeking some occupation in a warm climate.

Accidents from Pilocarpine in Croup.

In Paris *Médical*, No. 50, Dr. Bouchut thus observes: After reporting cases of croup in which favorable results have been obtained from pilocarpine injections, it is but fair to speak of the cases wherein those injections have produced serious accidents. Quite recently I have had an opportunity of experimenting with this substance on a great many children in the Hospital des Enfants Malades, and I have obtained no beneficial results worth mentioning. The bulk of my observations confirm what has already been said by Weiss, Neumeister, Kuster and many others. The only effects I have been able to discover are prostration and collapse, although I never gave one-third to two thirds of a grain daily, as recommended by Guttmann.

During my absence from the hospital two children were treated, and while so weak a dose as one-sixth of a grain was used, yet the most serious toxic effects were produced. A summary of these two cases will best illustrate the results attending this medication.

Case 1.—Girl, 6 years old; well characterized membranous croup. Treatment: Papaine, chlorate of potash, and ten drops perchloride of iron. After a few days of this treatment slight improvement. The same treatment was then continued, and in addition, a subcutaneous injection of pilocarpine was given. Profuse perspiration; no salivation. The following day another injection was given. Salivation now became abundant; perspiration very copious. The patient was seized with a violent chill; cyanosis of the face. The upper part of the body became cold, lower extremities moist. One or two attacks of vomiting. Two injections were given the next day and attended with similar results. The following day but one injection was given. Same symptoms. The throat appeared somewhat better, but the general condition was bad. Paleness of face, and great prostration. The daily injections were now discontinued. Vomiting and chills ceased; but the larynx became embarrassed; the cough grew croupy; the voice weakened, and asphyxia followed; owing to general depression, no operation was performed, and the patient died.

Case 2.—Female child, 2½ years old. Same general symptoms, and same treatment. The pilocarpine injections produced no vomiting, but were otherwise attended with similar results as in the first case, and the child died after a few days.

A Halfpenny Swallowed by a Child and Vomited Five Weeks Afterwards.

Dr. R. T. Jenkins reports the following case in the *Medical Times and Gazette*:—

A little boy, five years old, was playing with one of his relations. He seized a shawl which was on the sofa, put it to his mouth, and bit it. At the same moment he was attacked with a fit of spasmodic coughing, and a bronze halfpenny, which was observed to be upon the shawl, was suddenly drawn into his mouth, carried backward during a forced inspiration, and sucked down, unintentionally. A physician was called in at once, and made an unsuccessful attempt to extract the coin with forceps. The third day the child complained of pain at the pit of his stomach. Vomiting after taking food and after the paroxysms of coughing became more frequent. The child lost flesh and became much weakened. He could only retain a very small portion of food at a time.

One morning, five weeks afterward, the child vomited. In the matter vomited the mother observed a solid substance, dark in color, and thickly coated. She put it into water, and after much washing she found it to be the missing halfpenny. It was much corroded, but the distinctive features of the coin were visible on both sides.

The child has not suffered any further inconvenience.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A NEW DEPARTURE IN MEDICAL ETHICS.

The recent action of the New York State Medical Society is worthy of more than a passing notice, since being, as it was, the deliberate act of the representative body of our profession, of the greatest State in the Union, its action, we are forced to conclude, will carry much weight, and will be very potent for good or evil, as the wisdom or error of its judgment may predominate. It was the first time in the history of medicine that a formal and powerful assault has been made upon the barrier that separates the old from the new school. It was claimed by some of the more ardent advocates of professional ethical liberality, that the code of ethics ought to be abolished entirely, and the broad rule be substituted in its place, that every physician should be required merely to "*act as a gentleman.*" This seems like going back to first principles, for upon this basis professional and civil law really has been erected. The golden rule of "*Do unto others as you would that they should do unto you,*" means nothing more than that you should at all times be "*a perfect gentleman.*"

But different men view the same question from different standpoints, and thus arrive at widely divergent conclusions. Hence has it been necessary to become more explicit, and reasoning up from the basis of the golden rule (common to all civilization), to enunciate certain definite rules for the guidance of men; to say you can do this, and you cannot do that. Since the origin of homœopathy, until the present day, a wide and impassable chasm has separated it from our school. Why? Because, as we had occasion to say in a recent issue, the two systems of treatment are antagonistic, they are irreconcilable, and one must be wrong while the other is right. There can be no half way business about it; homœopathy must be potent, or it must be valueless.

If, then, a man believes that the true system of combating disease is to found in the regular practice, how can he possibly tolerate homœopathy.

If he believes that it requires four or five grains of a certain drug to produce its therapeutic effect, how can he, without stultifying his avowed belief, admit that a small fraction of a grain of this same drug can produce equally beneficial results.

If he cannot give his honest adherence to this law of infinitesimals, how can he conscientiously openly countenance homœopathy, by consenting to consult with those who believe in and practice its teachings.

If, believing that it is wrong, that its agencies are incapable of curing diseased conditions, he still countenances and encourages it, so as to cause those who look to him for counsel and advice to rely upon its remedies and to place confidence in its practitioners, then does he indeed, as we have already said, become guilty of "*compounding a social felony.*" Because, by his action, he causes his followers to believe in that which he does not himself have any faith in.

To illustrate, familiarly: the physician who would refuse to have his wife, his children or himself treated homœopathically, would express by his refusal, louder than any words could do,

his disbelief in the efficacy of the homœopathic materia medica. If, now, such a gentleman should consent to consult with a homœopath, he would be doing wrong morally, since he would, for some motive or other, be doing for others what he would consider to be wrong for himself and his own.

There are, of course, two sides to this much-discussed question. There are some homœopaths who are so only in name. To further their own temporal interests, they make an open profession of this belief, while in truth they view disease from our vantage ground and combat it with our forces.

Now, when asked to consult with such a man, by consenting no crime is perpetrated against society, since by meeting him and deciding upon a course of treatment that you are sure beforehand will coincide with your conscientious views, you are not knowingly and willfully doing an injury to your fellow-man.

This seems to be the ground upon which the New York Society based its action, since the statement was made that homœopaths are to-day practically regular physicians in all but the name. This, however, is too broad a view, since there are at the present time many *Simon pure* followers of Hahnemann, with whom we can have no professional intercourse without prostituting our sense of right.

Again, even when we consent to consult with what we might call liberal homœopaths, we are not strictly acting the part of the "*perfect gentleman*," since the little monitor (*conscience*) within us constantly reminds us that we are countenancing deceit.

There must, then, be a right and a wrong. If the abstract principles of homœopathy are correct, then the fundamental doctrines of our practice must be based on false premises, and vice versa. If, as was stated at the meeting referred to, the disciples of Hahnemann do not now adhere to his teachings, but give their allegiance to our doctrines, then ought they to come out openly and manfully and embrace our faith. If they do not; if they still conscientiously adhere to the aborted but well meant reasonings of their apostle; if they still believe that the most minute doses and the most infinite attenuations are potent and requisite to cure disease, then must we, in the confident strength of our own faith, say they are wrong; that they are no doubt honest in their belief, but that their doctrines and dogmas are fallacious and impotent; and thus saying and believing, we cannot, in justice to ourselves and our fellow-men, openly countenance their practice.

We do not believe in violent denunciation of any honestly believing man; but we do maintain that there must of necessity be a right and a wrong to every question. If one man says, "You give too much medicine in every case; your doses are too large, and you reason from fallacious grounds," while his opponent answers, "Your doses are ridiculously small and cannot have any appreciable effect," one or the other must be wrong. It would be equally "*compounding a social felony*" for the conscientious homœopath to consult with the strictly scientific physician, as it would be to reverse the case.

Such legislation as the New York State Medical Society has seen fit to pass can remove the penalty from this wrong-doing; it can give the sanction of professional law to this social wrong; but it cannot remove nor disguise the self-evident fact, that when the conscientious believer in our principles and doctrines consents to meet at the bedside one whose belief and whose prospective methods of treatment he honestly considers to be useless or worse than useless, he is doing a social and moral wrong, he is sacrificing his conscience, and in doing so, is fully under the impression that he is doing his patient an irreparable injury. This action on the part of an influential society has opened the ethical door, through which many easy-going consciences can pass; but let us hope that the better portion of the profession will, as they always hitherto have, regard it honestly impossible to professionally meet those whose methods of curing disease they consider fallacious and invaluable. Liberality of belief, and tolerance of those who may differ from us in anything, is commendable, but conscience must never be sacrificed.

COMMISSIONS TO EXAMINE ADULTERATED FOODS AND ARTICLES OF COMMERCE.

Some articles that appear in this issue will direct the attention of thoughtful physicians toward the dangers to health that exist unsuspected in articles of diet, as well as in many different objects offered for sale. It seems strange to talk about disease of the liver in an oyster, yet you will note that such an authoritative source as the Chief Medical Officer of Health, of Dublin, has found such a condition to exist, and points out a green color of the oyster as diagnostic of the disease. Probably but few of our readers have ever seen this condition, but within a few days we encountered such an oyster, in a stew, and wondered at it, until we saw the article referred to. The oyster we noted was distinctly green, of a bright color all down one side.

It is well known that various articles of food are frequently adulterated, but attention has not been sufficiently directed to this channel. The physician who desires to produce the greatest amount of good and to cure the largest number of patients will do well to inquire into the articles of food that have been used by patients to whom he is summoned, and whom he finds suffering with vomiting, diarrhœa, or other symptoms of *acute indigestion.*

If due, as they are in the majority of cases, to the ingestion of some poisoned food, you must remove the offensive articles from the system. Anodyne and sedative remedies will do no good, since the foreign and poisonous elements, still remaining, will keep up the irritation of the stomach or bowels, while an emetic or a dose of castor oil will discharge the cause and allow the *vis medicatrix naturæ* to cure the sufferer.

Too little attention is paid to the influence of poisoned food in production of disease, and physicians are too much prone to peer too deeply into the etiology of many common disorders, when by the exercise of a little common sense the cause would be found to be staring them in the face.

Again, children's toys are often the cause of acute enteritis or gastritis, since they are generally coated with poisonous paints, which are licked off and swallowed, innocently and thoughtlessly. These few words are given merely to direct the attention into this channel, and to cause physicians to realize that many cases of acute departure from health are due to this cause. The question we consider of so much importance that we will in a future issue furnish a special report on the subject.

But the great question comes in, "How can we prevent such adulterations, and the use of such poisoned food?" In one way only, namely, by legislation, by the appointment of committees whose duty it shall be to examine into the quality of all articles offered for sale, and to decide whether or not they are in any way inimical to health. We desire to turn your thoughts in this direction, and to prepare you for our report.

Notes and Comments.

Nasal Calculi.

Dr. Rumbold made some remarks to the St. Louis Medical Society (St. Louis *Medical and Surgical Journal*) on this odd subject. The calculi are due to the formation of cretaceous masses. The samples he presented to the Society weighed four ounces; they were removed on different occasions, from a syphilitic patient, in whom the septum of the nose was destroyed, and the inferior turbinated bone partially gone, so that they could be grasped quite readily with an instrument. Their growth was very rapid.

Renal Lithotomy.

In the *Medical Times and Gazette*, Mr. Henry C. Butlin reports an interesting case of renal lithotomy. The patient had for several years suffered from severe attacks of neuralgia of the testis. After he was admitted into the hospital, the pain was discovered to be seated in the right side of the abdomen as well as in the testicle, and that the symptoms were rather those of renal colic than that of neuralgia of the testis. The urine contained crystals of calcium oxalate, occasionally a trace of albumen, but no blood or pus. The general health was fairly good. As treatment did not afford permanent relief, Mr. Butlin cut down on the kidney, through a vertical incision in the lumbar region. The kidney appeared to be healthy, but a calculus was discovered and removed from the renal pelvis. It was composed of calcium oxalate, was about as large as a filbert

and quite prickly on the surface. The patient made a good recovery, so that in two months he was discharged, entirely free from pain, and entirely well, except that a little pus was present in the urine. The wound was treated, as far as possible, like an ordinary lithotomy wound. The absence of blood in the urine, in this case, is especially remarkable, when the situation and nature of the stone is considered.

Xanthopsis.

At a recent meeting of the Clinical Society of London (*Lancet*) Mr. W. H. Kesteven read the following notes of a case of xanthopsis. On an exceptionally hot day, last July, a married woman, aged twenty-three, having exposed herself to the full heat of the sun, was seized with acute pain in the occiput, and found that she saw all things red and green. As the pain passed off, in the course of a day or two, this intense coloration diminished. The ophthalmoscope revealed the existence of a large patch of double contoured nerve fibres at the upper part of the disk of the right eye. This, when first seen, was very prominent, and gave evidence of the existence therein of some neuritis. The left disk was normal. The color vision of the left eye was normal, but with the right eye she saw all things yellow. This condition continued for more than three months, and then gradually passed away. The author suggested that the condition might be explained by the violent impression made by the rays of the sun impinging directly on the retina. The case was examined by two other gentlemen, who confirmed the ophthalmoscopic appearances described.

Poisoning by Chromate of Lead in Weavers.

Dr. Robt. C. Smith contributes the following cases to the *British Medical Journal*. Mrs. B., aged 30, a weaver in a cotton mill, has been unable to work for six weeks; suffering from great weakness, wandering pains in her limbs, and anæmia. Her gums show well marked signs of lead poisoning. No albumen in urine. She attributes her illness to the inhalation of a yellow dust that was given up from the yarns in the process of weaving an orange-colored cloth. She had always enjoyed good health before being employed on this class of goods, and stated that her fellow workers, when engaged on this kind of work, sooner or later sickened. Mary C., a weaver in the same mill, was seen a few days subsequently. The blue line was very distinct. Her breath was offensive, while the skin and conjunctivæ were of a distinctly yellow color. There was obstinate sickness and purging of dark, sap-green motions (probably stained with chromium oxide). Urine contained albumen and a trace of chromium, but no bile nor lead. This girl's sister presented the same line of symptoms. Some seventy similar cases were observed from the same mill. In one fatal case distinct traces of lead were found in the liver. Public opinion being aroused, pressure was brought to bear on the employers, who have since then caused the yarn to be more carefully dyed and prepared before being woven. The winders and weavers wear a muslin respirator over the mouth and nose when at work; and use hooks to thread the shuttle, instead of sucking the weft through its eye with the mouth. By these precautions, rigorously carried out, the operatives, though still weaving chromes, no longer suffer from lead poisoning.

In these cases, the yellowness of the skin was the first symptom to disappear, and the blue gums the last. He concludes that, after absorption, the dichromate undergoes decomposition within the blood; the lead being fixed in the tissue, while the chromic acid combines most probably with soda—a compound which is intensely yellow, and stains the liquor sanguinis and skin for a time; and finally leaves the body by the liver and kidneys.

Puncture and Aspiration in Intestinal Invagination.

We read in Paris *Médical*, January 28th, 1882, that Dr. Godfrey has treated a case of intestinal invagination as follows: The patient, a man 37 years old, was vomiting a greenish-yellow liquid having a most offensive fecal odor. His abdomen was distended, and very tender to the touch; and distinct fluctuation together with dullness were perceptible over the entire course of the colon. The umbilical region was somewhat tympanitic. Great tenesmus existed, and the efforts at defecation only resulted in the passage of a little bloody mucus. Having carefully ascertained that no hernia existed, the intestine was punctured, first in the left, then again in the right iliac region, the largest needle of a Codman and Shurtleff aspirator being used for that purpose. More than a pint of liquid, similar to that vomited, was thus withdrawn, and the patient felt somewhat relieved. Vomiting now became less frequent, and finally ceased. Morphine, first hypodermically, then by the mouth, procured sleep, and after three days the intestine had resumed its functions, and in less than a week the patient was again well.

Subcutaneous Injections of Iodoform in Syphilis.

The *Centralblatt für die Med. Wissensch.*, No. 44, reports that Dr. Thomann, having observed the good results attending the external use of iodoform in the treatment of certain syphilitic manifestations, was led to try if similar benefits could not be derived from it in the form of subcutaneous injections. He made use of a solution containing ʒiss of iodoform to fʒv of glycerine, and commenced with doses of grs. ivss; finding that these were well tolerated, he gradually increased them to grs. xj. He selects, in preference, recent cases in which sclerosis has not as yet caused irreparable disorders in any of the organs, especially in the lymphatic ganglions.

After ten or twelve injections, made on different parts of the body, he has observed a marked retrocession in the symptoms. No abscesses were formed, and only among a few patients were the injections followed by a slight sensation of pain, which, however, soon disappeared. The solutions used should always be freshly prepared.

Dementia and Idiocy.

M. Magnan, of the St. Anne Asylum, recently made a communication to the Soc. de Biologie, regarding a patient who had passed from a state of dementia to that of complete idiocy. He considers that in dementia the cortical lesions of the brain are not extensive, but that as they tend gradually to become complete, the patient, as the cerebral atrophy progresses, becomes more and more idiotic. Idiots are entirely oblivious to external impressions; they can neither observe, taste, nor hear; at least, external sounds have no influence over them; patients in a state of dementia, on the contrary, preserve in their state of intellectual feebleness some faculties almost intact. The patient presented by M. Magnan was at first in a state of dementia, but gradually lost the few words she remembered, and the peculiar swaying of the body from side to side, the indecisive, vague, frightened look observed in idiocy soon appeared. The results of the autopsy proved interesting; the right cerebral hemisphere was almost intact, but the left presented adherent meningitis, with considerable atrophy and diffused sclerosis about the vessels of all the convolutions, with the exception of the frontal and ascending parietal. As the patient was not hemiplegic, this was another proof in favor of the present localization of the motor centres. This observation would seem, also, to warrant another conclusion, viz., that the right hemisphere has but a feeble part in the intellectual value of the individual.

Scrofula and Tuberculosis.

The *Medical Times and Gazette* says that M. Grancher recently made to the Société Médicale des Hôpitaux of Paris an interesting communication on the above subject. The following are his general conclusions: 1. Tubercle is a fibro-caseous neoplasm, the development of which takes place in successive stages, during a longer or shorter period; this complete evolution may be accomplished in a few months, or it may last throughout the whole of life. It may, however, be arrested during the earlier stages, and never get beyond them. 2. Pathological anatomy and experimental pathology are to-day agreed to include under the term tuberculosis the greater number of affections called scrofulous, as *local* tuberculoses. 3. Lupus, and superficial inflammations of the skin and mucous membranes, the last resort of those who persist in regarding scrofula and tuberculosis as distinct, will probably be included in the same order in due process of time. 4. The necessities of practical medicine, which, after all, must first be reckoned with, do not permit all tubercular affections to be confounded together; on this account it is convenient to retain the word "*scrofula*" for those tubercular affections which are very slight and generally curable.

Severe Illness Caused by Ingestion of Cakes and Cheese.

The Dublin *Journal of Medical Science* says that early in January of this year a young woman and two children ate some ginger cakes bought in a small shop in a suburban village. Shortly afterwards they became very ill, with choleraic symptoms. One of the patients suffered from vomiting, one from severe abdominal pains, and all three from diarrhœa. The remaining cakes were examined for ordinary poisons, but none were found. They were soft, and had evidently swollen from their original dimensions. They were in great part covered with minute cryptogamic vegetations, composed of *penicilium glaucum*, and the blue *ascophora mucor*. On breaking into the cakes, several cavities were found in them, which were lined with fungi, most of which belonged to the species *ascophora nigricans*, but not a few were of a species that could not be identified. In addition to the moulds, there were numerous bacteroid bodies. A portion of the cake, weighing 135

grains, was kept for three hours in a water bath; it was then eaten by a mouse; another portion was subsequently given; the next morning the mouse seemed perfectly well. The same quantity, without being heated, was given to a mouse, and in less than two hours the animal died, death being preceded by diarrhœa and spasmodic action. It is probable that among the ordinary fungi which appear in decaying food, and which do no harm, there are occasionally moulds or other low forms of life—animal or vegetable—which are highly poisonous.

From the same source we note the case of a man and his children, who, having partaken of butter and cheese in the evening, became very ill during the night. The father awoke, four hours after he had taken his meal, with violent headache; vomiting and diarrhœa followed, and continued during the whole night and the following morning. The children—four in number—had suffered from the same symptoms as their father during the night, and three of them were affected with diarrhœa all the following day. The youngest child, aged three, *did not have vomiting*, but cried all night, and died early on the following day. A post-mortem revealed extravasated blood in the lungs, which were slightly congested. Left ventricle contained liquid blood; the right auricle contained numerous soft and recent clots. The abdominal viscera did not present any abnormal appearance that would account for death. The mother of these children, who had not partaken of the cheese, remained in her usual health. The cheese in question had a greasy texture, a yellowish hue, and an intensely rancid odor, combined characteristics which must always be regarded with suspicion. It is, perhaps, some chemical products of putrefaction and not fungi which cause rancid cheese to be noxious, for cheese is often in a putrescent state and remarkably free from moulds, while, on the contrary, mouldy cheese is often free from decided rancidity. (These two cases point two morals: 1st. When called to a case of sudden sickness, presenting symptoms referable to a deranged stomach or bowels, inquire into and examine the remnants of the last articles eaten. 2d. The necessity for the establishment of commissions to examine and analyze all articles of food offered for sale.—Ed.)

Illness Caused by Filth in Milk.

Dr. C. A. Cameron, Chief Medical Officer of Health for Dublin, reports, in the Dublin *Journal of Medical Science*, the following interesting facts concerning a hitherto scarcely noted cause of milk impurity. A specimen of milk was submitted to him for examination, which was believed to contain a toxic substance of some kind, for the following reasons: Three children who were in the habit of drinking largely uncooked milk, were taken sick. They presented furred tongues, and gastric symptoms, such as are usually present in the earlier stages of enteric fever. Temperature 104.5° F. The house was new, in a healthy location, and no bad odors had been noticed. The sanitary arrangements were in good order. The children had been healthy two days before. A general examination of the milk in stock was made; it presented a peculiar appearance, the cream which had risen to the surface having a deep brown color. A short time before the children's illness a similar brown stratum had been observed on the milk. Generally the milk presented no peculiar features. The composition was found to be—

Water	87.10 per cent.
Fats	3.56 "
Other solids	9.34 "
	100.00

It was, therefore, milk of good quality; but a microscopical examination of the cream taken from this milk revealed the presence of cow's hairs, minute particles of straw, and *débris* of organic matter in great abundance. There were numerous monads, vibrios, and bacteroid bodies. The odor of the cream was slightly but distinctly unpleasant. A subsequent visit to the dairyman was made. He at first loudly protested that he sold only *pure* milk. The cows were examined and found healthy; no cause whatever could be discovered for the impurities. Finally, on pressing the milk vender for an explanation, he stated that the cows were milked early in the morning, by his nephew, who had no light with him, and omitted to wash the teats of the cows before allowing their milk to flow into the milk pails. As some of the cows had lain down all night in such a way that their udders were in contact with the manure in or close to the channel courses, their teats were covered with filth. (A word to the wise is sufficient; this report demonstrates how easily good, pure milk can be rendered poisonous, and the remedy suggests itself at once to every intelligent man.—Ed.)

Treatment of Cardiac Asthma.

The *Union Médicale* states that M. Dujardin Beaumetz recommends the use of bromide of potassium in those cases of intermittent dyspnœa which are really a cardiac asthma, and

which are so frequently attendant on aortic affections. Owing to its action on the bulb, this salt will be found valuable in all conditions of dyspnœa and angina. Small doses of pure, crystallized chlorhydrate or bromhydrate of cicutine may be added to it. Iodide of potassium in progressive doses of from one to four grams (gr. xv–℥j.) is also serviceable in asthma from aortic affections. When the paroxysms moderate, the patient should only take about grs. xxij, daily. Another remedy, recommended by Professor Sée, consists in inhalations of iodide of ethyl. The patient should breathe from five to ten drops, five to eight times daily. Finally, subcutaneous injections of morphine have been found of benefit.

Special Reports.

NO. III.—INFECTIOUS DISEASES (Continued.)

As a fitting conclusion to our several reports on infectious diseases, we will give this week a summary of the remote effects of these diseases on children.

We are all aware, but we do not sufficiently realize, that many of the chronic derangements of children are due to the remote effects of infectious diseases. We all realize that fatal kidney disease, in not a small proportion of cases, supervenes as an effect of scarlet fever, and from this knowledge we gain a warning not to be disregarded, namely, that the sensitive and denuded cutaneous surface of the child convalescent from scarlet fever must be scrupulously protected from the action of cold until such time as it shall have put on a new covering.

We are also taught that various forms of paralysis are liable, frequently, to be manifested as sequelæ of diphtheria, and we are thus forewarned to be on the lookout for and promptly meet them when they do occur. But in a recent address, delivered by Dr. James Carmichael, extra physician to the Royal Hospital for Sick Children, at Edinburg, attention was called to the fact that we do not sufficiently note the influence of infectious diseases in the production of subsequent ill health. He says, "In the out-patient room of a children's hospital, the oft-repeated expression of '*falling*' or '*wasting away*' is one of the most frequent which the physician hears. A careful physical examination, in a large proportion of cases, will be sufficient to reveal the presence of some disease. Not unfrequently, however, such exploration fails to throw any light on the case, and it is only after an attentive consideration of its history, and a more prolonged study, that we can arrive at any conclusion as to its nature."

The truth of this picture must be evident to every practicing physician, who, surely, has often had brought to him children who, their parents say, do not seem well; they offer no definite symptoms, neither can the most careful examination reveal any positive disease. They do not eat well; they start and cry out in their sleep; caring but little for play or the ordinary pursuits of childhood; they seem listless and languid, preferring to remain about the mother's knee, and being nursed and petted. The slightest indiscretion in their care and management will precipitate some acute derangement.

A careful and persistent inquiry into the past history of many of these cases will elicit the fact that at a greater or shorter interval they have had some infectious disease which, being regarded as one of the necessary concomitants of childhood, has created no alarm and has been forgotten, but upon refreshing the memory, it will be discovered that this condition of depraved health manifested itself shortly after the supposed complete recovery from the disease.

We know that all zymotic diseases most profoundly impress the blood; we might then imagine that in many cases this action upon and alteration of the vital fluid would so influence the various parts of the body nourished from it, as to modify and depress their vital activity to such an extent as to interfere with their thorough physiological life, producing thereby a condition of languor and imperfect performance of duty incompatible with perfect health, yet not sufficiently definite to constitute any particular disease.

If, however, such imperfect nutrition and incomplete vital phenomena are permitted to persist unchecked and unrelieved for a length of time, they may ultimately eventuate in irreparable disease of some vital organ. Thus, then, it becomes important that we should recognize and be warned against this possible future danger, that we may check it in its incipiency.

Dr. Carmichael tells us that the most common causes of chronic ill health in children are syphilis, rickets, and scrofula. They all act, of course, in the same way, and their gross pathology is easy of comprehension. They consist essentially, as we know, in a foul and poisoned condition of the blood, which we can readily conceive must poison and contaminate all the organs and parts it touches. He reminds us, that when we ask the question, "Has the child ever had any previous

illness?" the reply is usually in the negative; but when we supplement this by the question, "Has the child ever had measles, scarlatina, or whooping cough," an affirmative is at once given, thereby conveying the impression that mothers consider these diseases of little or no importance in the catalogue of their children's ailments.

Some years ago, a young physician of great promise, who had just graduated with high honors, was substituting for a medical friend who was resident physician in one of our hospitals. He was called upon to amputate a gangrenous limb. When cutting through the bone, the saw slipped, inflicting a slight wound on one finger. A few days subsequently he was seized with convulsions, and within seventy-two hours died of Bright's disease. The existence of the disease had been unsuspected, but it was remembered that some eight or nine years before he had scarlatina, from which his family then remembered that he seemed to never have thoroughly recovered, although they paid no attention to his condition before the supervention of the convulsions, since he presented at no time any definite symptoms of ill health. It would seem, here, that the disease had remained dormant for years, until excited and stirred into fatal activity by the absorption into the system of the gangrenous poison from the amputated limb.

In obedience to the generally recognized law, that organs or functions develop tendencies to disease in direct ratio to their normal or physiological activity, Dr. Carmichael notes that in children the acute diseases are a fruitful cause of initiating chronic disturbance of function or disease in certain organs, or systems, which present great functional activity in the early periods of life. He says that a certain proportion of those children who are attacked with measles, scarlatina, or whooping cough, suffer immediately or remotely from chronic ill health, which may or may not be accompanied by some organic affection of internal organs. Among the more ordinary conditions, he notes *general debility*, as a result of which the child may fall a prey to some other disease, the ravages of which, once started, the debilitated system is unable to resist. Lymphatic glandular affections may follow any of these diseases.

During convalescence from measles and whooping cough we must ever remember that the bronchial lymphatic glands have, during the course of the disease, been enlarged and irritated, and that they may remain so, giving rise to ultimate caseous degeneration of the glands, debility, and death, or may cause secondary general tuberculosis, which usually causes death in children by meningitis; and this brings him to say a few words as to the diagnosis, more particularly, of enlarged bronchial glands. These glands are situated in the posterior mediastinum, in immediate relation to the bifurcation of the trachea and the roots of the lungs. On the surface of the body the site of the former corresponds anteriorly to the first bone of the sternum, posteriorly to the second or third upper dorsal vertebræ. The glands are ten or twelve in number, and lie in the cellular tissue of the posterior mediastinum, in close relation to the trachea and brouchi. It may be at once stated, as a fact generally admitted, that, although considerably enlarged, their recognition by physical exploration is usually attended by negative results. One of our most careful clinical observers of disease in children states, "In order to afford signs of its presence, the disease of the glands must be sufficient to produce considerable enlargement; for unless their size is so much increased as to produce derangement of function in neighboring organs, the lesion is one which cannot be satisfactorily diagnosed." It may be stated, likewise, with tolerable probability, and my own experience bears this out, that in the larger proportion of all cases met with, and in those in which serious results follow the chronic glandular hyperplasia, the enlargement has not been sufficient to cause injurious pressure on neighboring structures. If this be the case, the usual signs which are described as denoting the presence of these buboes, such as venous turgidity and lividity of the face and neck, dyspnœa and spasmodic cough, and dullness, either anteriorly over the upper sternal region, or posteriorly, will not be present.

In general terms, it may be stated that, given a child who has suffered within a year or eighteen months previously from either of these diseases, and who is in a chronic state of ill health, undergoing progressive wasting, with no symptoms of disease of any internal organ, the probable existence of bronchial phthisis, more rarely of mesenteric phthisis, may be suspected. The two following cases from the experience of Dr. Carmichael thoroughly illustrate this position:—

Alex. McD., aged 2½, was brought to the Royal Hospital for Sick Children, on 8th of February 1881, suffering chiefly from debility and wasting. The mother stated he was a healthy child till he was attacked by measles, a year ago, since which he has never been quite well. He was a breast baby. There were no marks nor history of syphilis. On examination, all organs yielded negative results as to signs of disease. There was nothing positive in regard to the child's con-

dition but progressive emaciation. He was under careful observation for five months, and the course of the case was watched with interest by the gentlemen attending the out door clinic. I ventured to express an opinion, many weeks before the child died, based upon the general history of the case, and its negative clinical features, but more particularly on account of the antecedent history of measles, that subsequent to this disease, and as a direct result of it, bronchial glandular hyperplasia had been established, followed by caseation of the glands, and that probably general tuberculosis would follow, or was then actually existent. The subsequent history of the case amply verified such a diagnosis, the child succumbing to meningitis a few weeks after. On post-mortam examination, the tracheobronchial lymphatic glands were enlarged and caseous, the lungs, liver, and other organs studded with small, gelatinous-looking, so-called miliary tubercles, and the brain presented all the usual characters of meningitis. This is a very ordinary history, as the records of our hospital testify.

Marion C., aged 3 years and 8 months, was brought to the hospital on August 10th, 1880. She was a healthy child, and never suffered from any illness until six months ago, when she was attacked with pertussis, which lasted for four months. Since then she has been quite free from cough, but her general health has not been satisfactory. On examination, she was not an unhealthy looking child, being fairly well nourished. She was, however, languid and listless, had little appetite for food, the bowels were irregular, the muscular system was soft and flabby. Ordered emulsions of cod liver oil, regulation of diet, and change of air, if possible. On the 13th inst., or three days after examination, she began to be troubled with vomiting, coming on at irregular intervals, without reference to the ingestion of food. On the 15th inst. drowsiness supervened, and she sank rapidly, from meningitis. On post-mortem examination, the brain presented all the usual signs of basic meningitis and general subarachnoid effusion. The ventricles contained about six ounces of fluid. The lungs, liver, kidneys, and peritoneum were studded with tubercles. Broncho tracheal glands enlarged and caseous.

Nasal catarrh, that may persist throughout life, is a frequent sequel of measles and scarlatina.

Thus, then, we comprehend the dangers that may arise, subsequent to an attack of any one of the zymotic diseases. This knowledge teaches us in no uncertain terms the lesson that we have not always cured our little patients, when we have safely piloted their delicate bodies through the text-book stages of a zymotic disease. We must have them under our observation for a long time, and in all cases where any degree of debility persists for two or three weeks after the subsidence of the disease proper, it must be removed. For this purpose, cod liver oil, the syrup of the phosphates of calcium and iron, as well as other tonic treatment, must be resorted to. Indeed, it would be a good rule, and one that would insure your being on the safe side, were you to place every child convalescing from an infectious disease upon this tonic treatment, and surround it with the best possible hygienic measures.

Correspondence.

Diphtheria.

Ed. Med. and Surg. Reporter:—

It will not be amiss, in connection with the concise study of this disease presented in the "Special Reports" of your issue of the 4th instant, to draw a brief practical lesson.

The glory of medicine as a science and art, is to avert and heal disease. To these points all its lights converge. A properly adjusted experience is present knowledge, and a guide to future wisdom.

As a study and basis of experience to others, I wish to again call attention to the value of the liquor potassa in this disease. In June, 1876, my experience to that time was given in the Boston *Journal of Chemistry*, and reprinted in the Reporter. The results of additional experience were given to Dr. F. M. Peterson, of Greensboro, Alabama, and by him incorporated in his thorough and exhaustive article on the subject in the "Alabama State Medical Transactions," for 1881. Two cases have been treated since then, making a total of forty-three cases, with three deaths; a limited experience compared with many others, but wide enough to be at least suggestive and hopeful.

How this treatment may bear the test of other localities, with different climatic surroundings, I cannot say, but it is to this point of test that I wish to lead the minds of the profession, as one of the at least hopeful means of waging successful war with this fearful disease.

The usual method adopted by me is as follows: Suspecting or recognizing the disease, if a purgative is needed, which I have not often found to be the case, I give, preferably, as the safest and surest purgative, a full dose of calomel, suitable to the age of the patient. If the patient is an adult, twenty drops of the liquor potassa are given in half a glass of water every three hours, with proportionate doses for children; two drops being the dose at same interval for a child one year old. Between each dose I give, each hour, full doses of the syrup of lacto-phosphate of lime, freshly made; the formula for making is given below. The dose for an adult is one or two tablespoonsful at the above mentioned interval, increasing the dose with increase of debility. It may be diluted or not, as preferred. Full proportionate doses for children. I rely on this as a powerful adjuvant. It has almost incomparable value in staying the waste of the system in all asthenic diseases, and in promoting assimilation; and besides, I am led to believe, has some specific value in neutralizing the poison.

We have here two medicines, one tasteless in its dilution, the other exceedingly palatable; great points of advantage in themselves. The liquor potassa destroys the vitality of the poison,

the syrup of the lacto-phosphate of lime sustains, prevents breaking down, and probably, has a specific control over the poison. What more can we desire in the therapeutic art, if a larger experience shall confirm the value of this method of treatment. Later in the disease, when the membranous exudation has given way, I use this syrup of lacto-phosphate of lime in its emulsion with cod-liver oil. The emulsion to be freshly prepared. If the heat of the skin is great, the body is freely and often anointed with bacon rind, till the temperature is reduced. No local applications are made to the throat, internally nor externally, save the free use of the bacon rind. For diet, boiled sweet milk, buttermilk, and some of the malt extracts. Lemonade is also given freely, when desired, as a drink.

As a matter of course the physician will investigate the cause. In one of my fatal cases, evidently decaying Irish potatoes under the house produced the disease. This practice of storing away Irish potatoes under our houses, elevated from the ground on brick pillars, as they are, and open for free access of air, is a common one in our latitude, eminently productive of organic disease, and need only be mentioned to be condemned. If this article shall lead others to a full and careful test of the practical value of the above course of medication, my object will be gained. It will be found, by crucial test, that other remedies are adjuvants. I believe the liquor potassa, from my own point of observation, to be the nearest approach to a remedy yet known, to destroy the poison of the disease.

SYRUP LACTO-PHOSPHATE OF LIME.

Mustard in the Treatment of Smallpox.

ED. MED. AND SURG. REPORTER:—

Just before the close of the war I was called to prescribe for a Confederate soldier, suffering with great nausea. A large mustard plaster was ordered to be placed over the stomach. A few hours afterward my attention was directed to an eruption covering the part where the mustard had been placed. It was a well developed case of smallpox. There was no eruption on any other part of the body. The pustules were well developed, with the characteristic pit. I did not have another opportunity to try it, but believe a mustard plaster applied to any part of the body will bring out the eruption twenty-five to thirty-six hours earlier than usual, so that a diagnosis can be made on the first day of the fever. I believe it possible to invite all the eruptions to any part of the body, and thus avoid the pitting of the face. And in malignant cases, where the poison produces death before the eruption appears, the mustard might possibly bring out the eruption and save the patient. The experiment is easy and harmless.

E. S. LYNDON, M.D.
Athens, Ga., Feb. 20th, 1882.

The Prevention of the Zymotic Diseases.

ED. MED. AND SURG. REPORTER:—

In carbolic acid, I think, the profession will find a preventive of the zymotic diseases; I refer particularly to three diseases: diphtheria, scarlet fever, and typhoid fever. When an epidemic of either of these occurs, and my plan of prevention is thoroughly carried out, the result has always been, either the progress of the epidemic has been checked entirely, or the severity of the disease lessened; a malignant type changed to a mild one; individuals and families who adopted my suggestions would have the disease in a light form, or escape entirely, while those who did not receive my treatment would contract it in a malignant form. My custom is, when a case of either of the above mentioned diseases occurs, to commence immediately the internal administration of carbolic acid (with directions that the clothing, person, etc., should be washed in a weak solution of the acid) to all those of a family or community that I judge would be likely to contract the disease. These statements may not be credited, Mr. Editor, and all I ask is that skeptics and critics will try my method before they condemn it. W. W. BROWN, M.D.
Kabletown, W. Va., Feb. 15th, 1882.

NEWS AND MISCELLANY.

Canal Boat Children.

In France no child under fourteen years of age is allowed to live or work in a canal boat, and no woman is permitted to live in the barge cabins without special permission from headquarters, although there is ample space for them. To prevent breaches of the law in these respects, special officers are appointed by the Government to board the boats, barges, etc., at certain points.

When a Lady's Horse Shies.

Those of our readers who reside in the country and are accustomed to depend on horses for the transportation of themselves, their wives and daughters, may derive a valuable hint from the following, which we take from the London *Lancet*:—

It is an unpardonable crime to mount a lady—however good a rider she may be—on a horse that shies. If, however, an animal addicted to this serious habit is intentionally ridden by a female, she should sit on that side that gives her the least risk of being unseated. Young girls are trained to ride some days on one side and some on the other side of their ponies, for the sake of their figures. It would be well if women kept up the practice. This alone would give a lady a firmer seat on a horse, and by simply adapting the saddle to the peculiarity of the particular horse when a risk was intentionally run, the danger of accident might be minimized. Most

horses shy more from one side than the other, and many only on one side, as when the sight is failing in one eye. It is curious that even practiced riders, who are well versed in horse flesh and manners, scarcely ever take the trouble to examine the eyes of the strange horses they mount casually.

Cleanliness next to Godliness.

An exchange says, "To the peasant, the Russian bath, a moist variety of the Turkish bath, is a 'second mother.' When Peter the Great was advised by foreigners to introduce hospitals and dispensaries into Russia, he was wont to reply that Russians needed nothing else as a health-giving remedy against mortal ills, when they had baths."

Flowers in Sleeping Rooms.

A correspondent, commenting on a note in our issue of February 11th, on "*Flowers in Sleeping Rooms*," refers to some papers on this subject written by Dr. J. M. Anders. These papers take the ground that growing plants are beneficial to health, and are very excellently written. It would seem, however, that this question has never been definitely settled one way or the other. It would appear to be an open question, upon which discussion is desirable.

Gout.

The London *Medical Times and Gazette* thus replies to a correspondent: Touching gout, the great Sydenham consoled himself with three satisfactory reasons: 1. That more wise men had it than fools. 2. More rich than poor. 3. That it was more incident to men of strong than of weak constitutions. Some wise men think it dangerous to cure gout, and Shakespeare, who had a good notion of physic, says, in *Cymbeline*:

> "One that's sick 'o the gout had rather
> Groan so in perplexity, than be cured
> By th' sure physician, *Death*."

The Coming Sanitary Congress at Newcastle-on-Tyne.

Recently a deputation from the Sanitary Institute of Great Britain, consisting of Professor F. S. B. F. DeChaumont, M.D., F.R.S., Chairman of the Council, Mr. G. J. Symons, F.R.S., Professor W. H. Corfield, M.A., M.D., Chairman of the Exhibition Committee, the Secretary, and the Curator of the Exhibition, met the Mayor and Sanitary Committee at Newcastle-on-Tyne, to make arrangements for the Congress and Exhibition which is to be held by the Institute in that town in the autumn of this year. Several buildings were visited, and suitable ones selected for the various meetings and the Exhibition. The Congress and Exhibition will be opened on Tuesday, September 26th.

Green Oysters.

Dr. Gaillard, in the *Annales d' Hygiene* (Dublin *Journal Medical Science*), states that oysters acquire, by confinement and other conditions, a green color, which is probably due to disease of their livers. This diseased state appears to cause an increase in their adipose tissue, and, consequently, of their succulence. These green oysters command a high price, therefore the art of adulteration has stepped in, and oysters are artificially colored by dipping them in solutions of copper salts. In a dozen oysters colored by this method chemical analysis demonstrated the presence of 0.147 grain of metallic copper, a quantity capable of exciting vomiting and other perturbations. Persons who had eaten only seven of these artificially colored oysters felt unwell. The suggestion is made to wash the suspected oysters with a solution of acetic acid and the dipping of a needle into the washings. If copper be present, it will be deposited upon the needle.

Maternal Impressions.

Dr. F. J. Baker, of Lockport, N. Y., sends us a circular letter asking information on the following points; if any of our readers can assist him by sending any knowledge they may possess on the subject to the above address, they will be assisting the progress of science:—

1st. Have any cases come to your knowledge or observation, of fœtal deformities or "marks" attributable to mental impressions on the mother during pregnancy?

2d. Have you any knowledge of cases tending to establish the doctrine of materno fœtal symmetry, bearing particularly on ante-natal education?

Any information you may be able to give which will assist us in cultivating this interesting field of study will be most gratefully acknowledged.

South Africa as a Field for Medical Practice.

Jas. S. McDonagh writes to the *Lancet*, under date of January 30th, 1882, as follows:—

The Africans have an idea that the medical men who go out to settle among them are the refuse of home produce, and unless a man has superior qualifications or settles in a remote part of the country, they are chary in seeking his advice. In Cape Town, seventy-five cents for a visit and medicine is the common charge. Living is very high; he has known as much as one dollar and ninety cents to be paid for a cabbage. The day when men went out to South Africa and made fortunes in a few years is passed. The inhabited parts are overstocked, and unless a man settles in these with the best qualifications or proficiency in some specialty, *e. g.*, ophthalmic surgery, and can afford to wait, he had best remain at home.

Items.

—The Boston *Medical and Surgical Journal*, says: "L'entrée est défendue aux dames" is certainly not a suitable inscription to be placed over the portals of a University; and it is satisfactory to be assured by the President of the Boston University, in his last report, that a phrase so often seen over certain apartments in French railway stations will be denied a place upon the front of the University building.

OBITUARY NOTICES.

DR. THEODORE LEWIS MASON.

Dr. Theodore Lewis Mason died at his residence, in Brooklyn, N. Y., of pneumonia, Feb. 12th, 1882. Dr. Mason was born at Cooperstown, Otsego County, New York, September 30th, 1803. His father, Daniel Mason, a lawyer, was a lineal descendant of the famous John Mason, one of the founders of Norwich, Connecticut, and for years a member of the Council, the Lieutenant-Governor, and Commander-in-Chief of the military of the State. His mother was a daughter of the Rev. Dr. Lewis, of Greenwich, Connecticut. He graduated from the College of Physicians and Surgeons of New York in 1825. After practicing a while in Wilson, Conn., he moved to New York, and settled in Brooklyn, in 1834. Dr. Mason manifested great interest in the treatment of inebriety as a disease, and was President of the Inebriates' Home of Kings County, and later was President of the American Association for the Cure of Inebriates. He was a resident Fellow of the New York Academy of Medicine, a member of the Medical Society of the County of Kings, and was President in 1842 and 1843. He was a permanent member of the American Medical Association and of the Medical Society of the State of New York. He was one of the founders, life member, and Director of the Long Island Historical Society, a member of the American Colonization Society, and its Vice-President in 1874.

ROBERT BRIDGES, M.D.

Dr. Robert Bridges, Emeritus Professor of Chemistry in the Pennsylvania College of Pharmacy, died at his residence, No. 119 South Twentieth street, February 23d, 1882, in the seventy-sixth year of his age. Dr. Bridges was a native of this city, and a constant resident during all the years of his active and useful life. He graduated at the University of Pennsylvania, both in the department of arts and in that of medicine; the latter in 1828, six years after the establishment of the College of Pharmacy, an institution to which he was afterward to render services so valuable, faithful, and so long continued. His services were held in such high esteem by all associated with the College of Pharmacy that when increasing years and infirmities warned him to tender his resignation, he was at once elected Emeritus Professor of Chemistry, and so continued during the brief remainder of his life.

Dr. Bridges being a physician, as well as a chemist, was a fellow of the Philadelphia College of Physicians and Surgeons, and for many years, in addition to the duties of his professorship, discharged those of librarian to the last-named institution. He was a man of active mental constitution, a patient and systematic thinker, and a polished and lucid writer, and the scientific journals of the country were enriched by many contributions from his pen. He was also the American editor of *Fowne's Chemistry*, which, by its extensive circulation, made his reputation national.

For the last two years Dr. Bridges has been a sufferer from a complication of diseases, which, as became plainly evident some weeks since, could have no other than a fatal termination. In private life Dr. Bridges was a gentleman of high intelligence and kindly manners, proceeding from genuine goodness of heart and innate benevolence. To his immediate relatives he was tenderly attached, and his house was as a home to those near and dear to him; but, singularly capable as he was of appreciating household happiness, he never married.

DR. SAMUEL WHITALL.

Dr. Samuel Whitall, one of the best known physicians practicing in New York city, died February 18th, 1882, at his home, No. 607 Lexington avenue. A week previous he was attacked by malarial fever and acute bronchitis. His death was sudden and altogether unexpected. He was but forty-one years old, and has generally enjoyed excellent health. Dr. Whitall was born in Woodbury, N. J., and was educated in the drug business in Philadelphia. He went to New York soon after his majority had been attained, having graduated in medicine. He was a member of the Pathological Society, and of the Physicians' Mutual Aid Association. For many years, and until the time of his death, he was Superintendent of the Colored Home Hospital, First avenue and Sixty-fifth street. During the latter years of his life he became a frequent contributor to medical journals, and his opinions were quoted as authority. He was prominent in the Orthodox Society of Friends, and was noted for his charities. He was a widower, and leaves no children.

—Victor Theodore Junod, the celebrated Swiss doctor and author of medical works, is dead. He was born in the Canton of Vaud, in 1804. When a young man he went to Paris and became known for his inventions of cupping glasses and therapeutical bell-glasses. He received the Montyon prize in 1836, and the grand prize of medicine and surgery in 1870, besides several medals at the London, Paris and New York exhibitions.

—Lucius L. Pettengill, the last surviving son of Samuel C. Pettengill, M.D., died at Hancock, Delaware County, New York, on the eighth day of February, 1882, in the fortieth year of his age.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

Lecture.

ASYSTOLISM.

Delivered at the Hôtel Dieu.

BY M. RAYMOND,

Professor Agregé of the Paris Faculty.

Gentlemen—I wish to call your attention again, to-day, to two patients, one of whom died a few days since.

The autopsy was made before you, and as you may remember, there existed chronic lesions of the lungs.

Again, toward the close of life the patient presented somewhat remarkable delirious symptoms, which merit careful consideration. The other patient, now before you, has heart disease, and presents also chronic pulmonary lesions. I will commence my lecture by the consideration of her clinical history.

The patient is thirty-nine years of age, and entered the hospital August 30th. She suffers, as you observe, from intense dyspnœa. The respirations are short and very frequent, fifty-two per minute. The face presents a generalized yellowish tinge, but the cheeks have the bluish coloration of cyanosis, rendered more evident by the jaundiced color of the rest of the face. The eyelids are œdematous; the neck appears tumefied; the lips have a well marked, bluish, cyanotic aspect. The venous system is dilated over the entire body, in the neck, at the upper part of the chest and in the hands and feet, which are cyanosed and cold. The lower limbs also are considerably swollen and œdematous; all the natural prominences have disappeared, and the slightest pressure with the finger causes pitting. The patient complains of vertigo and ringing in the ears. At night she is obliged to remain propped up with pillows, and enjoys but a broken rest, for her slumbers are disturbed by terrifying dreams. From time to time she suffers from intense pain in the right hypochondrium. This pain, not limited to any special point, is augmented by pressure over the hepatic region and extends at the back to the right shoulder. The pulse is small, miserable, and irregular, hardly perceptible, and sometimes intermittent. The heart impulse is diminished, and sometimes even it appears entirely absent, or at least so feeble as to be scarcely perceptible.

The cardiac dullness is somewhat augmented transversely. The heart sounds are so feeble as to be distinguished only with difficulty, but there is no evidence of murmur. The second sound is more marked than usual over the pulmonary artery.

There is no asystolic murmur at the right of the sternum or near the epigastric region. The jugular veins are prominent, but there is no venous pulse, nor is there any trace of hepatic pulsation.

The patient is not only in a veritable state of orthopnœa, she has also abundant muco-purulent and yellowish expectoration.

The methodic examination of the chest gives the following results: Over the sub- and supraspinal fossæ on the left side there is almost absolute dullness on percussion over a space of about fifteen centimeters. At the central part of this side of the chest the sound is normal, perhaps slightly tympanitic; at the extreme lower part is a narrow zone of dullness.

Percussion over the anterior aspect gives the same results as posteriorly; dullness at the upper part of the chest, but normal sound over the remainder. On the right side of the chest the *sonority* is normal over all the superior part, before and behind; there is a zone of slight dullness at the inferior part posteriorly.

On auscultation tubular breathing is found on the left side, at the points where dullness is most marked; it is most evident with the inspiration.

There exists, also, bronchophony at these points, but no râles are present, even when the patient coughs. On the contrary, over the rest of the chest sonorous and sibilant as well as subcrepitant râles are found. These last are most marked inferiorly and particularly on the right side.

Anteriorly, blowing respiration is found under the left clavicle, and râles similar to those detected posteriorly, but much less numerous, are found over the remainder of this aspect of the chest.

The abdomen is soft, somewhat tympanitic and painful in the hepatic region; the tongue is normal; appetite and digestion good, and but slight tendency to constipation.

The liver, manifestly augmented in volume, extends a space of two finger breadths below the false ribs; the spleen also is somewhat enlarged.

The urine is dark-colored and scanty, but presents no traces of albumen.

When she entered the service her morning temperature was normal, 37.6° C., the evening temperature being always somewhat higher, about 38° C.

According to the patient's very lucid statement, there exists no hereditary predisposition to any particular disease. When fifteen years of age she suffered from a violent attack of acute articular rheumatism, affecting all the large joints. The attack lasted two months, and since that period she has frequently suffered from slight rheumatic pains, particularly when fatigued, and these pains were accompanied by palpitation of the heart. At 22 years of age she had a slight attack of jaundice, lasting five weeks, and ten years later a second attack, of much longer duration. It was at this period that she commenced to cough, and the limbs for the first time became swollen. Since then she is much subject to similar symptoms, œdema of the limbs and repeated attacks of bronchitis, which lasted four months, without affecting her general health.

When respiration became too painful and the limbs very much swollen, she entered some hospital service, generally during the month of April, and after fifty or sixty days' sojourn she was able to leave the hospital, apparently cured, and again take up her daily labor until the same symptoms supervened again.

On the 12th of August these symptoms appeared more formidable than ever before, and were accompanied with considerable hæmoptysis; about two large glassfuls of red, spumous blood were expectorated; this was the first attack of hemorrhage the patient experienced. For the last six months the menstrual flow has been arrested. Such, then, is the clinical history of our patient; it now remains for us to interpret the signs and symptoms observed.

You have recognized, with great facility, that the patient is in a condition of asystolé; as to this fact there is no room for doubt.

But is the term asystolism or asystolé a good one? Is it sufficiently clear, regarded by the light cast on the subject by contemporary research? I do not think so. Beau, who first used this term, said: "We give to these symptoms the name of asystolé, comprising under this denomination, also, the insufficiency of the systole, which is the point of departure, and the sole cause of the asystolic state."

The following objection may be urged against this theory: if such be the case, how does it happen that asystolism is not observed in cases where the heart alone is affected, as, for instance, in the form of myocarditis observed in typhoid conditions. Is it not well known that the heart beat is frequently strong, although the pulse be feeble? And, no matter how feeble the action of this organ, is it not always sufficient to dilate the arteries? How can the multiplied visceral dropsies in asystolism be explained, unless we admit a feeble state of the vessels themselves, which have become incapable of properly emptying the encumbered capillaries, because they are, like the heart, in a state of degeneration? These reflections, according to M. Peter, are true, clinically, and physiology, by demonstrating the reciprocal action exercised by the heart on the vessels, shows that the new theory is well founded. I would advise you to read, on this subject, the interesting pages devoted by M. Vulpian, in his work on the vaso-motor system, to the relations existing between the heart and the blood vessels; you will be able then to understand why, since there is physiological reciprocity, there must necessarily exist morbid reciprocity.

At every point of view, the term cardio-vascular asthenia, proposed by M. Rigal, is preferable to asystolé, and as this author has remarked, the

heart beats may be frequent, unequal and irregular, without cyanosis, dyspnœa, congestions or dropsy; it is the condition to which M. Sée has given the designation arythmia.

If the peripheral circulatory apparatus is normal and the heart diseased, the general circulation may remain good; but if the lesion exists in the small vessels, the slightest trouble in the action of the heart will provoke cardio-vascular asthenia and all its consequences. Some patients with very slight cardiac lesions have all the phenomena of asystolism; while others with considerable disease of the organ do not suffer from them; because the first are young and the peripheral circulatory system is in good condition and capable of extraordinary resistance; the others, on the contrary, are aged, at least as regards their blood vessels, which are hard, atheromatous, and in a degenerated condition. With such a condition, one may easily understand why, when the heart becomes feeble, from whatever cause, the symptoms of asystolé suddenly supervene. M. Peter has, in his clinical lectures, called particular attention to these facts.

Remember, then, that it is necessary, particularly when forming a prognosis, to examine at the same time, and with the greatest care, the condition of the peripheral circulation in conjunction with the state of the heart itself.

Our patient has invariably suffered, at the debut of her asystolic attacks, from pain in the hepatic region; on two occasions she has had jaundice. This happens frequently, and when a large number of patients with cardiac disease are interrogated, it will be found that the mode of development of the symptoms due to the cardio-vascular asthenia is always the same for the same patient. You have probably noted that, though there is considerable œdema, no albumen is found in the urine of this patient, and no symptoms of cerebral disturbance are present. The clinical history of the asystolic attack may vary, and does vary much in different patients; sometimes there is predominance of the indications toward some particular organ, and in such case the symptomatology proper to the organ most affected dominates. This fact, first brought to notice by M. Grancher, is of interest.

We should now seek for the point of origin of the very marked cardio-vascular asthenia observed in this case. Modern research has brought to light many new causes capable of inducing asystolism, and I will briefly enumerate them.

Asystolism may be: 1st. Of cardiac or cardio-vascular origin. In such a case, a direct perturbation of the heart itself is the primary cause. Asystolism is a phenomenon which supervenes suddenly, and is generally due to a chronic lesion of the organ.

Much less frequently observed in aortic disease, asystolé may come on suddenly, without obvious pre-existing lesions of the heart or vessels, in patients debilitated by the habitual abuse of alcoholic stimulants, or living under unfavorable hygienic conditions; the heart is, in such individuals, overworked.

Under this category may be classed M. Debove's case, where an asystolic attack supervened on violent palpitations in a patient with exophthalmic goitre. Asystolism is also met with: 2d. In pulmonary diseases. Very rarely observed in acute affections, although cases have been reported of its occurrence in acute pneumonia, by Graves and Grisolle, and in acute phthisis, by M. Parrot, it is frequent in the chronic diseases of these organs, in emphysema, chronic bronchitis and pulmonary sclerosis. It also occurs: 3d. In gastric and hepatic affections; these clinical facts have been recently demonstrated by M. Potain. This teacher has shown that, if the heart reacts on these organs when compensation is broken, reciprocally, the disease of these two organs may induce asystolé, by acting on the right heart, probably, through the agency of the great sympathetic and pneumogastric systems. 4th. Asystolism is observed in kidney diseases, particularly in interstitial nephritis. In this last, three factors are at work in producing the symptoms; the generalized endarteritis, hyperplasia of the connective tissue of the heart and the gastric derangements so frequent in Bright's disease. 5th. In functional nervous diseases, as in hysteria, I know of no case where asystolism occurred, although the attacks of cardiac palpitation are frequently very violent, without, of course, any organic disease of the heart. MM. Peter and Letulle have, however, recently observed, during an attack of acute articular rheumatism, a veritable inflammation of the pneumogastric, the neuritis being characterized by pain on pressure along the side of the sterno-mastoid muscle, in the epigastrium and at the internal portion of the left intercostal space, and accompanied by a marked asystolic condition, characterized by general lividity of the cutaneous surface, the lips being cyanosed and bluish, the conjunctiva yellow; the pulse small and very frequent, 140 per minute: intense pulmonary congestion, etc. M. Huchard has observed somewhat similar phenomena in patients suffering from violent attacks of angina pectoris. 6th. In vascular diseases asystolé is frequent, as in atheroma of

the arteries, and other forms of vascular degeneration.

Among all the causes of the asystolic condition, some will not come at all into consideration, in explaining the symptoms observed in the case before us.

Nothing in all the symptoms to which I have called your attention points to any renal, gastric or hepatic disease.

There is nothing to prove either that the asystolism is of nervous or vascular origin. The woman is young, she has no atheroma of the peripheric arteries, and no bruit over the aorta. We remain, then, in presence of two possible causes of cardio-vascular asthenia, the heart or the lungs. In this particular case we have the facts furnished by the patient, concerning the existence of anterior attacks of rheumatism, of palpitation, œdema of the lower limbs, etc., all of great importance.

When, in connection with these, we have repeated attacks of asystolé, diminution of the præ cordial impulse of the heart, transverse augmentation of the cardiac dullness ; notwithstanding the absence of valvular murmurs, which have disappeared on account of the feeble energy of the heart's action, you will conclude that the paroxymal dyspnœa is of cardiac origin, for the pulmonary lesions are not really of sufficient extent, and are manifestly of too recent origin, to be regarded as the cause of the cardio-vascular asthenia.

What are the signs of pulmonary disease present? The signs discovered on percussion and auscultation are sufficient to prove the alteration of the pulmonary parenchyma, but this alteration does not appear to be of the same nature everywhere.

There are evident signs of bronchitis, such as sonorous and sibilant râles and the expectoration ; there is also œdematous congestion of the two inferior lobes, characterized by slight dull ness on percussion and fine subcrepitant râles, but besides this the apex of the left lung seems to be the seat of a special alteration. You have noticed how marked was the dullness and over how large a space it was evident.

Auscultation over these points demonstrates the existence of rude, blowing respiration, together with exaggerated *sonority* of the voice ; in a word, all the signs of pulmonary induration are present.

Of what nature is this induration? Is it a case of ordinary phthisis localized at the apex? I do not think so, for, habitually, tuberculosis is disseminated to the right and left, and in this case the general symptoms and the evolution of the malady are little in accordance with such a supposition. Can it, then, be a case of primary and unilateral cancer of the lung? This supposition is still less tenable, for in such a case there would exist almost certainly infection of the lymphatic glands, or at least there would be intense pain with sanguinolent sputa, and perhaps symptoms of compression. There are no symptoms of bronchial dilatation, notwithstanding that our patient has been for years subject to attacks of bronchitis. The existence of bronchophony and exaggerated thoracic vibrations, as also the nature of the cough, are against the existence of localized chronic pleurisy.

In fact, chronic pneumonia would alone seem to explain or be in unison with the stethoscopic phenomena. And, in effect, in my opinion, there is simply a fibrous metamorphosis of a part of the superior lobe of the lung.

It is much more difficult to determine whether this fibrous metamorphosis is the result of lobar pneumonia or of broncho-pneumonia. Against this last supposition is the fact that there is no bronchial dilatation ; a symptom which, according to Charcot, is characteristic of chronic broncho-pneumonia. It is true that there is nothing in the morbid antecedents of the patient, although she has had frequent attacks of bronchitis, which would permit us to affirm that she has formerly suffered from acute pneumonia. Nevertheless, it is from this order of ideas that the causation of chronic pneumonia must be sought. It is well known, in effect, that among the best demonstrated causes of this malady are those which render the system feeble, such as old age, diseases which induce cachexia. as malarial poisoning, albuminuria, alcoholism and diseases of the heart. As regards this last the authors are not all agreed ; some considering that diseases of this organ frequently induce chronic pneumonia, others claiming that there is not sufficient proof of this assertion.

I am of opinion that there exists no very plausible reasons for eliminating organic diseases of the heart from the causation of chronic pneumonia. The case at present before us seems to me conclusive ; and last year, in this same amphitheatre, I presented the lungs of a woman, forty-four years of age, asystolic, with disease of the mitral valves. Anteriorly she had had an attack of true acute pneumonia. At the autopsy the inferior and superior lobe of the left lung were found the seat of gray induration ; the pulmonary tissue was hard and elastic, entirely impermeable to air, sinking immediately in water.

This part of the lung, with the pleura covering it thickened and fibrous, appeared retracted. Microscopic examination demonstrated that the walls of the alveoli were considerably thickened by fibrous tissue; a few alveoli here and there were filled with a granular substance. There was no trace of bronchial dilatation, nor of cavities of any kind. I have observed two other very similar cases, and I think that in certain cases organic heart disease has a very evident pathogenetic influence.

However that may be, it is certain that in the present case the pulmonary induration of the left apex does not suffice to explain the asystolism. On the other hand, some of the signs indicate recent pulmonary alterations. As I have already said, the asystolé in this case is of cardiac origin and this is the fifteenth attack from which she has suffered.

What is the organic heart disease in her case? It is from the present clinical condition of the patient and from the mode of evolution of the symptoms that a response to this question must be sought. Notwithstanding the absence of murmur, all the symptoms point to mitral disease. The general symptoms, partial and generalized cyanosis and œdema, and the local phenomena, the small, miserable, intermittent pulse, the absence of soufflé, all are proper to mitral affections. I consider, then, that we have here a very grave case of mitral disease. The prognosis is extremely serious, on account of the accentuation of all the phenomena of the asystolic attack, and it is to be feared that this will prove the last.

You have observed the treatment I instituted: I first recommended the most absolute repose, physical and mental. On account of the marked feebleness of the heart, I have given wine, rum, coffee, and easily digested aliments, as the appetite was still good. As heart tonics, I administered $\frac{1}{30}$ of a grain of digitaline, in granules, per diem with subcutaneous injections of ether as an excitant. To relieve dyspnœa, I applied, several times, dry cups and sinapisms to the chest. Dry frictions over the lower limbs were practiced. I gave diuretic drinks, milk, and on account of the constipation, a few purgative enemata. I have not bled the patient, although general bleeding sometimes affords relief, because she is so weak that I feared to induce syncope.

[This patient died some days later, and the lesions found at the autopsy were as follows:—

The heart was enormous, the left auricle being as large as the fist of an adult. There existed typical mitral insufficiency, with considerable hypertrophy of the left ventricle.

There was œdematous congestion of the inferior lobes of the lungs and chronic inflammation of the mucous membrane of the bronchial tubes. There existed fibroid sclerosis of the superior lobe of the left lung.

No traces of chronic pleurisy, but the pulmonary tissue was hard and resisting, sinking in water. On section the exposed surface is brown and dry, traversed by thick, dark lines.

Histological examination shows the walls of the alveoli much thickened by fibroid tissue. There was no bronchial dilatation, no trace of tubercles. The liver was congested and hard; the spleen also indurated and retracted. The kidneys and other abdominal organs were normal. There was no cerebral lesion.]

I will speak more fully concerning the other patient in a future lecture. It was a case of chronic pleurisy with sclerosis of the lung; the patient presented toward the end of life a condition approaching asystolism with violent delirium, necessitating the application of the strait-waistcoat. At the autopsy we found, as I had predicted, considerable cerebral œdema, induced by the asystolic condition. There existed also numerous adhesions between the parietal and costal layers of the pleura, and almost complete sclerosis of the lower lobe of the right lung; the heart was normal.

Communications.

PROLONGED RETENTION OF THE PLACENTA.

BY GEORGE HAMILTON, M.D.,
Of Philadelphia.

In a late number of the Medical and Surgical Reporter is recorded a case of "Long Retention of the Placenta," taken from the *Lancet*. From the statement made, the retention lasted about seven or eight months, a circumstance so unusual as not only to surprise, but, possibly, to suggest doubt as to the accuracy of the report. Yet, if an extended examination be made of the earlier or more recent records upon this subject, the cases will no doubt be found to be more numerous than is generally supposed. Retained placenta, similar in duration to that quoted, has, in my practice of half a century, occurred but once.

It may thus appear that this feature of obstetrics can be of only minor practical importance, and so in fact it is, as a general proposition. The number of such cases actually recorded is, probably, small in proportion to what

it would be if practitioners would faithfully furnish to the medical journals, for publication, the cases of this character which may have occurred in their practice. When retention of the placenta does occur, whether in the early or at a later period of pregnancy, and continues for an unusual length of time, it assumes a degree of importance that entitles it to the earnest consideration and cautious judgment of the accoucheur, that he may be enabled to discover, if possible, the proper method of treatment; for it is to be remembered that on this point various and antagonistic opinions are entertained.

The case coming under my observation was that of a lady residing in the country. She was the mother of two children, and when advanced about two and a half months in her third pregnancy, was attacked with severe labor pains, attended with great discharge of blood. On my arrival the hemorrhage and pain had nearly ceased, many large clots had been thrown away without examination, and thus it was uncertain whether the embryo had escaped or not. About the tenth day she left her bed, having neither pain nor discharge of blood, resumed in part her household duties, and so continued during nearly three weeks, when a similar attack ensued, the pains more violent, but the discharge very much less than in the first attack. Upon examination, as in the first instance, nothing of an after-birth could be detected, yet the symptoms strongly indicated its retention, so that a longer confinement to bed was directed, nourishing food given, quinine and ergot were prescribed, the latter drug failing, on this and subsequent trials, to evince its specific action.

These attacks were repeated at indefinite periods until three months had elapsed, when I sought an office consultation with the late Dr. Naudain, of Wilmington, at one time United States Senator from Delaware. In this consultation his son, practicing medicine in the country, also took part. Neither of them had ever met with a similar case, and both concurred in opinion that if so small a placenta had not passed off in the first attack, it had gradually come away in shreds, by dissolution, or that it had been absorbed; so that the real cause of these repeated prolonged attacks might, with more reason, be attributed to a tumor, or to some special disease of the uterus. No material change in the treatment was proposed by them, nor was any made. Another month had passed away without essential change of condition, when a messenger was dispatched to West Chester, a distance of twelve miles, to summon Dr. Thomas, preëminent in experience and capacity, to the bedside of the patient. On being informed that four months had elapsed since the first attack, he expressed surprise, saying that while he had met with a number of cases of abortion in which the placenta was retained, none of them exceeded four or five weeks, and were finally passed without serious injury to the patients, and without active interference. After careful examination Dr. Thomas said he found nothing to explain the real condition of the patient, and that while it seemed improbable that any considerable portion of the placenta could be so long retained, he did not regard it as impossible, and in this view I concurred, satisfied, as I was, that the woman was advanced about two and a half months in pregnancy, that the first attack was precisely what we are accustomed to see in abortion, and that each subsequent attack was radically but a repetition of the first. The only proposition by the Doctor was to give rather larger doses of ergot and quinine; and before leaving he expressed the opinion that the case would terminate favorably, and the issue justified this prognosis, but not until two months additional had passed away (with the attacks as usual), making six altogether. On the first of the last three visits made to the patient, the nurse, with smiling face, met me at the door, and called out that she had good news for me. She then said that during the previous night the lady had one of her usual attacks, lasting not so long as usual, and leaving her very abruptly, entirely free from pain. On withdrawing the cloths upon which the discharges had been received, the afterbirth, to the infinite joy of patient and nurse, was found. It had not come away in shreds, it had not passed off in decomposition it had not withered away, nor had it been absorbed, but was nearly as large as the average placenta of a two and a half months abortion; and this was fully explained by observing the side of the placenta attached to the uterus, the numerous vessels severed at the moment of expulsion, and through which the vitality, consistence and bulk of the placenta had been maintained.

In this connection another case of placental retention, of different and more exceptional character, may deserve notice. A lady some years ago desired my attendance for the third time, in confinement. The patient told me that she had yet to go from three to four weeks to complete the full term. After a short and easy labor, she gave birth to a still-born female. The child was at least as large as the average at full period, the head somewhat deformed, the features

of the face idiotic in expression. Waiting a moderate length of time, and no pain occurring, gentle traction upon the cord had no sooner begun than, to my great surprise, it came away, although it appeared to be of average strength and thickness. Ergot was then resorted to, in full doses, but failed to produce pain, nor was there any normal pain of the least importance. On introducing my hand, for the purpose of delivery, it passed readily along between the placenta and the uterus, until it approached the fundus, upon the left side, where the tissue of the placenta became so hard and tough, and the adhesion to the uterus so firm, that prolonged effort at separation was ineffectual. On withdrawing my hand, about half of the placenta was grasped and brought away without any difficulty, for the lower portion of the after-birth was simply a pultaceous (incoherent) mass, void of adhesion to the uterus, but without the odor or appearance of putrescence. The patient was informed that a portion of the placenta still remained, yet she was perfectly calm, although alone, her nurse not having arrived, and expressed the hope that another effort might be successful. This was accordingly made, and while more force was employed than before, and far more than I had ever before or since employed, no impression whatever was made upon the tough and hardened mass occupying the left side of the fundus. Before withdrawing the hand, as much as could be separated from the lower portion of the firmly adherent placenta was brought away, leaving from one-fourth to one-third attached at the point designated.

Fortunately there was no disposition to hemorrhage, nor is this strange, when we call to mind the actual condition of the lower part of the placenta, without adherence to the uterus, and the singular condition of the remaining portion, both in reference to composition and adhesion.

With the cheerful consent of the patient, who placed implicit confidence in my judgment and sense of duty, I left her, and called upon Dr. Beesley for the purpose of consultation. In a large practice he had never met with such a case, but called to mind several instances of retained placenta lasting from one to five weeks, all of which were abortions, of from six to twelve weeks. All these did well, and he strongly approved my purpose to avoid further effort at separation. On my way back to the patient, the late Professor, Dr. Joseph Carson (then Accoucheur to the Obstetric Department of the Pennsylvania Hospital) was called upon, who, when informed of the nature of the case, and the two forcible attempts unsuccessfully made to remove the remaining portion of the placenta, said that the situation of the woman was sufficiently critical, without rendering it more so by substituting for the gentle and most probably successful efforts of nature an irrational and reckless amount of brute force. Before arriving at the residence of my patient a third gentleman was spoken to upon this exceptional case, who, although not an adept in obstetrics, was eminent for his mechanical genius, skillful in contriving surgical appliances, and decidedly remarkable for his ardent, impetuous temperament. The history of the situation of the woman seemed to him alarming, and, after enumerating the sources of danger, hemorrhage, inflammation, pyæmia, putrescence, blood poison, or the formation of a tumor, he ended by saying that he saw no hope for the patient but in the removal, if possible, of the adherent portions of the placenta, without regard to the amount of force required. On reaching the home of the patient, from whom I had been absent an hour and a half, I found her comfortable, suffering no pain of any moment, free from hemorrhage, and when informed of the result of the consultations with Drs. Beesley and Carson, she fully acquiesced in our decision. Before leaving I again introduced my hand, and found no change in the situation. After the fourth day, daily visits only were required, and upon the expiration of the second week the visits were discontinued. As may readily be conceived, the lady, as well as myself, was anxious to know what might result, sooner or later, from the retention of so large and firm a portion of the placenta. It was for this purpose enjoined upon her, from the first day, to have every discharge, whether from the bowels or bladder, closely examined, to ascertain its precise character, and that, so soon as the nurse left, she herself would continue these examinations for at least three months. That this injunction was sedulously obeyed there is no reason to doubt, and when the time had expired, she informed me that she had neither felt nor observed anything different from what had occurred after the two previous confinements. It seems probable that absorption was at work in this case, but whether in this or some other way, nature dealt so gently and effectually, in preparing for another conception, that in less than two years she was again quickly delivered, at full term, of a living child, followed as before by favorable recovery.

As stated above, cases of this kind are so seldom met with that, in a practical point of view, they may, perhaps, be regarded as of slight

importance; yet, if we bear in mind the indisposition of a large proportion of practitioners to report cases, even if specially abnormal, the inference is legitimate that the number is not inconsiderable. Few as they may be, they are of value, especially at the present time. From year to year there seems to be an increasing distrust in the restorative power of nature, and this distrust in a *vis medicatrix naturæ*, is especially manifested in reference to the ability of woman to accomplish, without active interference, that work to which she is specially destined. Influenced by this idea, many physicians are ready to declare impossible that which a few cases of the character just cited prove to the contrary. That placental retention, either in the earlier or later stage of pregnancy, may be so complicated with other adverse conditions as to imperatively demand active and prompt interference, is manifest; while on the other hand it is to be feared that, in the absence of such conditions, the mere apprehension of impending danger in one or another form above named may have suggested and led to the employment of measures, manual or instrumental, that might well have been delayed until their necessity had been more clearly established. In conclusion, we would commend to the serious consideration of those whose faith is weak in the conservative and restorative power of nature, the noble, eloquent, and reverential apothegm of him who has worthily been called the Father of modern surgery, Ambrose Paré, "Je les pause, *Dieu les guérit.*"

SMALLPOX AND VACCINATION.

BY JOHN T. HUDDLISON, M.D.,

Of Glen Mills, Pa.

The Philadelphia *Inquirer* of February 3d contains an editorial notice to the following effect: "Hon. P. A. Taylor, member of Parliament for Leicester, flatly denied the assertion of Dr. W. B. Carpenter, that vaccination is a protection against smallpox. Mr. Taylor says the scourge comes in an epidemic form, at different periods, and when the contagion is in the air the mortality is only reduced by superior hygienic arrangements. He shows by official reports that the plague has recently been as general and as deadly in London and other cities where vaccination is compulsory or universal, as it was before the alleged preventive was used, etc., etc. He makes a strong appeal to Parliament to repeal the Compulsory Vaccination Act, which he believes gives no protection against smallpox, but introduces *vaccine tuberculosis* and other terrible diseases into the human system." He says, "The only way to check the scourge is by '*isolation*,' and cites the condition of Malta, 'where, some years ago, the smallpox appeared; the garrison was *isolated* (the italics are mine) and all the troops revaccinated, but before the year closed over one hundred soldiers were attacked by smallpox and a large number died, even under the best treatment." He neglects to inform us whether or not these deaths occurred among the new troops sent to refill the previously decimated ranks. From his own report, his proposed remedy is utterly worthless, and he might just as well let us retain the one that most of us have confidence in.

I have been engaged in the practice of medicine for considerably more than half a century, and, for a private practitioner, have had pretty extensive experience in the treatment of smallpox and in vaccination, and in noticing the progress of the disease from point to point, and have become convinced that smallpox is never epidemic in the strict meaning of the word, but that the contagion is conveyed in emigrant ships, railroad cars, mail bags, infected paper stock, clothing and other fomites, and, but for very short distances, by the atmosphere, as, in fact, its progress across the American continent is commonly in the face of the prevailing winds.

The origin of smallpox is not known; but it is said to have existed in China and Hindostan more than 1000 years before the birth of Christ, and made its way into Arabia in the year of the birth of Mahomet, 569. Pursuing the track of armies, we find it raging in Egypt in 640, and subsequently, following the victories of the Saracens, in the eighth century, through Italy, Spain and France. By the Saracens the disease was communicated to the Crusaders, "who caused its spread throughout Europe" (*vide* Morse's "History of Smallpox"). There was no smallpox in the New World before its discovery by Columbus, in 1492. It was introduced into St. Domingo in 1517. Three years later, in one of the Spanish expeditions from Cuba to Mexico, a negro, covered with the pustules of smallpox, was landed on the Mexican coast. From him the disease spread, with such desolation that, within a very short time, according to Robertson, three millions and a half of people were destroyed in that kingdom alone (*see* "Wilson on Skin Diseases"). In all this, nothing is or can be ascribed to epidemic influence.

I most emphatically deny that there is any such disease as *vaccine tuberculosis*, or that either

smallpox or vaccination carry any other disease into the human system. They are essentially skin diseases, whose course is determined in a limited number of days, whereas tuberculosis is known to affect every other tissue in the body, and so far as known, is the result of a hereditary diathesis, is not contagious, cannot be communicated by inoculation, and is a lifelong disease. Vaccination, therefore, never introduces other "terrible diseases into the system," as the Hon. Mr. Taylor *believes*, but may, like scarlatina, measles, or any other cause of reduction of the vital force for a time, afford opportunity for the development of certain other diseases, as eczema and nettle rash, that have been lying dormant in the system and are ready to break out on the slightest provocation; but these instances are comparatively rare, and are of small moment when the almost certain exemption from the infinitely greater evil of smallpox is to be considered.

In regard to *compulsory vaccination*, I do not know where Mr. Taylor gets his figures; but according to the statistics of Hoffmann, "before vaccination was made compulsory the death rate from smallpox in England and Wales was one in 25 nearly, while in Prussia (where it was compulsory), of an average of a million of deaths, only one in 122 was from smallpox;" also that "the soldiers and seamen of England, being better protected, were almost exempt, being only one in 2000 in the army, and even less in the navy."

Of the efficacy of vaccination as a prophylactic I entertain no doubt. I was vaccinated in 1802, with virus obtained from the late Dr. J. Redmond Coxe. I attended the medical lectures in the University of Pennsylvania, in the years 1822–3–4, when smallpox and varioloid prevailed extensively. The students in the class, nearly 500 in number, were, for the most part, revaccinated. There were a few cases of varioloid in the class. A student who had been previously *inoculated* took smallpox and died; the only fatal case. Wishing to test the durability of the remedy I refused to be revaccinated; I attended the clinics at the Pennsylvania Hospital and the Almshouse, which were teeming with smallpox patients, and have since treated the disease in its worst forms, and have as yet escaped infection. On one occasion I attended in a family where out of six children only one escaped, and he was the only one who had been vaccinated. I could multiply instances.

Medicine not being considered an exact science, although by aid of the microscope and vivisection it promises to become so in the near future, it has not as yet satisfactorily explained why vaccination prevents smallpox any more than it is known why the passage of an electric current will reverse the poles of a magnetic needle. For the present the facts are sufficient for all practical purposes. Many persons entertaining views pretty similar to those of the honorable Mr. Taylor, in order to escape the danger of contracting sundry bodily infirmities through the use of humanized virus, resort to *bovine* lymph, regardless of the dangers of rinderpest, murrain, or the acquiring of a gramnivorous appetite.

If smallpox is ever stamped out, it will be through compulsory vaccination aided by the strictest quarantine; but, of course, it must be universal.

Hospital Reports.

UNIVERSITY HOSPITAL.

A Clinical Lecture, delivered

BY WILLIAM PEPPER, M.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

Reported by Wm. H. Morrison, M.D.

The Diagnosis of Simple Catarrhal Fever—Typhoid Fever.

Gentlemen:—I have to-day brought this case before you, and later I propose to show you the Frenchman with typhoid fever, who has presented some very striking changes in his condition since you last saw him.

This girl illustrates, in an excellent way, some of the points of differential diagnosis in regard to the continued fevers, as well as some very interesting and practical points in pathology. I shall briefly give you her history.

She is an Irish girl, 20 years old. Until the 9th of this month she was well. At that time she was suddenly taken sick, with violent headache, pain in the back, fever, delirium, loss of appetite and tenderness over the stomach, but no diarrhœa at that time. She remained in about the same condition until the fifth day of the attack, when she was admitted to the hospital. On admission, her temperature was 102.5°; pulse 116; and respiration 24 in the minute; the pain in the head and back continued; she wandered at times; the tongue was red at the edges; pointed and coated posteriorly with a yellowish-white fur; the bowels were loose (she may have taken purgative medicine before she came here); they were opened twice in twenty-four hours; the stools were light in color; the abdomen was still tender. The next day her condition was about the same. On the succeeding day the bowels had become quiet. She has remained in somewhat the same condition, except that there has been a gradual improvement in her

up to the present time, the morning of the 17th, the eighth day of the attack.

You will at once see a resemblance in this case, in some of its aspects, to a case of typhoid fever, but you will, I have no doubt, at once see marked points of distinction. You will not rarely come across cases where it is difficult to distinguish clearly whether you have a case of simple continued or catarrhal fever, or one of the specific fevers, particularly typhoid. I mean by simple continued fever, a febrile affection which is directly associated with a catarrhal inflammation of the mucous lining, chiefly of the stomach and bowels. We may, of course, have catarrh of the respiratory tract, and with it fever; but these cases are characterized by such marked physical signs, that they never give rise to any confusion; but the cases in which there is catarrhal inflammation of the mucous lining of the stomach and bowels, with febrile action, do often resemble typhoid fever of a mild type, and are frequently taken for cases of that disease.

Let us then consider in what particular they resemble each other, and in what particular they differ.

We find that, as a rule, catarrhal fever has a shorter duration, anywhere from nine to fifteen days, or even in some cases to twenty days. Secondly, the fever is, as a rule, not so high as in typhoid fever. There is the same fluctuation between the morning and the evening temperature, but as a rule, the evening elevation is not so high as in typhoid; nor does the temperature show that peculiar tendency to vary in successive weeks of the disease. In typhoid fever we have a lesion which occurs in successive crops; the follicles enlarge, ulcerate, and then slough; but they do not all do this at the same time. First one group enlarges, reaches maturity, ulcerates, and sloughs, then another group passes through the same change. We have thus a peculiar course of the temperature in each week of typhoid fever. We find, in the same way, that the other symptoms, particularly the eruption, follow this same fluctuating course.

Again, although in simple continued fever there is a continued fever with marked daily variations, the disease is wanting in some of the characteristic symptoms of typhoid fever. There may be in catarrhal fever moderate distention of the abdomen; there is usually a tendency to looseness of the bowels; the stools may be of a yellow color, resembling closely the stools of typhoid fever, so much so that it is often impossible to distinguish between the two; but the degree of distention of the abdomen is rarely as great as in typhoid. The coats of the bowel are not so much involved; there is not the same degree of paralysis of the muscular coat; there is, therefore, not so much distention of the bowel.

In catarrhal fever the diarrhœa is rarely so severe and uncontrollable as in typhoid. There is scarcely ever any hemorrhage, and if any, it is very trifling.

Again, there is an absence of any characteristic eruption in this disease. In typhoid fever, about the seventh day there appear, on the abdomen for the most part, the peculiar, little, oval, rose-colored spots. In catarrhal fever they do not appear.

Bleeding of the nose, which occurs frequently in typhoid fever, rarely occurs in catarrhal fever. This is a much less characteristic symptom of typhoid fever than some that I have mentioned and some that I shall mention.

Bronchial irritation we may of course have, because the catarrhal trouble which affects the stomach and bowels may also affect the respiratory mucous membrane. The presence, therefore, of a loose cough, with evidence of bronchial irritation, will not, in itself, enable us to distinguish, with any degree of certainty, between the two diseases.

The nervous symptoms in simple catarrhal fever are rarely grave. In an average case of typhoid fever the mind is dull, there is marked hebetude; questions are answered slowly; as the disease goes on there is apt to be delirium. As the case goes on the patient may pass into a state of marked delirium, or, on the other hand, into a state of deep stupor. These symptoms are common in marked cases of typhoid fever. In catarrhal fever the patient may be a little dull, reluctant to talk, and will lie quietly, as long as he is left alone; or there may be a little tendency to wander; but there is rarely the marked nervous symptoms that I have described as occurring in typhoid. In very nervous subjects, in those whose nervous system is easily thrown off its balance, catarrhal fever may cause marked delirium.

You see, therefore, that there are between the two diseases points of distinction and points of resemblance. The differences being to a considerable extent merely those of degree; and were this all you can readily see how difficult it would be to distinguish between a marked catarrhal fever and a mild typhoid fever.

In addition to these differences of degree, there are actual and specific differences, namely, the duration of the disease, the peculiar fluctuations of the fever and the absence of special eruption. Upon these latter points we often have to base our diagnosis, and not rarely you will have to hold your judgment in abeyance for a certain length of time before making the diagnosis.

There are actual differences in the cause and in the mode of onset. Typhoid fever we recognize as depending upon the introduction into the system of some form of poison, from some source, by some route, probably taken in by drinking water, or inhaled into the lungs, and which, entering the system, sets on foot changes in the blood, especially lesions in the glands of the intestine, going on to ulceration, and peculiar changes in the spleen. The development of typhoid fever is slow. The poison gains access to the system; there is a period of incubation, and then the gradual development of symptoms.

Catarrhal fever has quite a different beginning. In the majority of cases the symptoms develop rapidly. In this case the patient speaks of having been well until the 9th of the month. She was then suddenly taken sick, with headache, pain in the back, fever and delirium.

If we knew, or could study the circumstances under which the disease arose, we might receive some light as to the nature of the case. If we found that this woman had been exposed to bad hygienic conditions, if the air she breathed had

been contaminated by the emanations from drains or sewers, if she had been subject to depressing causes, which would render her more susceptible to the typhoid poison, we might suspect that she was suffering from typhoid fever. If, on the other hand, we had found this trouble coming on after exposure to changes of temperature, or draughts, or getting the body chilled, or after some acute indigestion, with at the same time exposure, we would have reason to think that there was no septic poisoning, but that it was an ordinary catarrhal attack.

In this case, everything, the onset and the character of the symptoms, appears to indicate that this is a case of simple catarrhal fever.

This is the ninth day of the attack, and just the time, if it were typhoid fever, for the eruption to appear; the other symptoms should be developing, and the fever rising; but instead of this, we find that the pulse is 84, and the temperature 99°. In typhoid fever it is rare to have the temperature go down to 99° until the morbid process has run its course. When the lesions have terminated, the ulcers cleaned, and the irritation subsided, the fever will fall, and not till then.

We find to-day that the tongue is cleaning. It is moist. It is a little red and the papillæ are enlarged. There is a little white coat on the back. It still evidences distinct irritation of the gastro-intestinal mucous membrane; a tongue of that kind on the ninth day of typhoid fever would be unusually favorable. There has been no disposition to diarrhœa for several days. She has no appetite. I now examine the abdomen, to determine the presence or absence of pain. Even when you are not sure that the case is typhoid fever, I would beg of you not to knead and press the abdomen too hard. Do not poke the tips of your fingers into the right iliac fossa, to try to develop pain or gurgling. You are poking precious and tender tissues, and you had better do it very gently. It does you no good to develop pain, and it may do your patient a vast deal of harm. It does you very little, if any good, to develop gurgling. It simply indicates that there is air and liquid in the bowel, and this condition may occur in diseases other than typhoid fever. There seems to be a little hyperæsthesia over the bladder. There is no distention of the abdomen. There is not a trace of eruption. There are a few little brown freckles. There are a few sudamina, *i. e.*, little drops of sweat caught under the epidermis. They have no special value whatever.

It would seem, therefore, that the patient has simple continued fever, of a catarrhal origin, without special typhoid poison associated.

Sometimes you will find that these cases will run on for twenty days. In such cases you will readily understand how difficult it would be to state positively that there is no typhoid fever present. You should be very cautious how you make such a statement, for if you say there is no typhoid fever present, it will not be deemed necessary to adopt the same careful treatment as in that disease, but if it should be typhoid fever, your want of care may cause the death of the patient, from hemorrhage or perforation. If you err, let it be on the side of safety. If you are not perfectly sure that it is a case of catarrhal irritation, with continued fever, call it mild typhoid, treat it as such, and insist upon the patient remaining in bed until the period that typhoid fever requires has elapsed. Keep the patient in bed for thirty days, so as to diminish the possibility of the rupture of a latent ulcer, causing the patient's death.

As to the pathology. It is very interesting to consider how long this fever can be kept up without, as far as we know, any special poison in the blood. It has become too much the custom, when a patient has fever which is not readily accounted for, to suspect blood poisoning. Blood poisoning is one of the fashionable topics of the present day. It has been taken up, not only by the profession, to apply to many cases of obscure disease (for if you say a patient has blood poisoning everybody is satisfied), but it has also been taken up by sanitary engineers, plumbers, and the people at large. Constantly, when attending a case where the febrile action is at all obstinate, you will be asked, "Doctor, is there not danger of blood poisoning." Local lesions have caused fever from the beginning of the world, and will do so as long as the body retains its present construction. Before you bring into the explanation of a case such a mysterious agent as blood poisoning, be sure that there is no local lesion present sufficient to explain all the symptoms. Do not neglect to make a minute physical examination of every organ.

As we go on in our clinical studies, I shall be obliged to return time and again to this topic, that local diseases excite general disturbance, that they implicate the whole system, and that, if neglected, they may give rise to the gravest general disease.

It is excessively interesting to see how a simple local lesion of a mucous membrane, without, as far as we know, any septic element, may keep up a continued fever of this character for so many days. "Yes," you may say, "but do not the secretions undergo change and become poisonous and is not some septic matter absorbed from the bowel which has an influence on this fever?" I have no doubt but that there may be, in certain cases, such an occurrence. I am inclined to think that a patient who has catarrhal fever, whose intestines are filled with matters ready to undergo fermentation and putrefaction on the slightest change, may have admitted to the system a minute amount of the typhoid germ—the typhoid ferment—possibly so small an amount that, if the system were in perfect health, it would be cast off and cause no trouble, but finding a suitable nidus, it develops and passes into the system, giving rise to a typical attack of typhoid fever. The typhoid fever poison must be very widely distributed. I fancy that through the system of nearly every one of us some of it has passed at some time; but it will undoubtedly act very differently and will produce very different results, according to the state of the bowel and the state of the system. An amount which would be eliminated readily when the system was in perfect health, will, if it finds the bowels containing matter prone to decomposition, and forming a suitable pabulum for it, go on developing and give rise to genuine typhoid fever. I

have frequently seen cases apparently of simple catarrhal fever occurring under unfavorable circumstances run into typhoid fever. Though I do not intend to assert that simple catarrhal fever can turn into typhoid fever from the absorption of ordinary putrefactive material from the bowel. As far as we know, the special typhoid poison must be admitted to the system and gain entrance to the blood.

But in this case, and in many of these cases, we have no right to suspect the least absorption, either from within or without. The fever is the result of irritation of the epithelial layers of the mucous membrane and of the terminal nerve fibres, and through these fibres, of the heat producing centres of the higher part of the nervous system. It is the same sort of fever that we have produced by local lesions everywhere.

If this is the case, you will see at once how enormously important is the treatment of these sorts of cases; and not only that, but you will begin to comprehend how very important, even in cases where there is blood poisoning, and also a local lesion, is the treatment of that local lesion. In typhoid fever, where there is a local lesion as well as blood poisoning, it is very important to address remedies to the cure of that lesion. Here we have a much simpler matter, for if we remove the irritation of the bowel the symptoms will at once improve.

Let me at the commencement of our studies speak against the use of purgatives at the beginning of febrile affections. What indication is there for any purgative dose at all? The chances are that the intestine is in a state of acute congestion, and you give a dose which if given to a man in perfect health would set up a degree of irritation that would make him miserable and sick for several days. The reply is, "I gave it to remove the morbid secretions, to carry off the effete matters." Very well; if you were dealing with a rubber hose, and could be certain that when you removed the obstruction it would remain out, there would be some reason in the treatment; but how do you know that while you remove the morbid secretions from one end of the bowel they will not collect at the other? The purgative you give may only increase the gastritis and duodenitis, and the morbid secretions will be thrown out more abundantly.

Be sure, therefore, that you have such an obstruction—such an accumulation as absolutely requires removal—and then graduate the dose to the condition of the stomach and to the irritation of the small intestine. I should treat such a patient expectantly for a short time. Then if I were satisfied, from the moderate distention of the bowel and the passage of one or two stools of an unhealthy character, that the inflammation of the mucous membrane was of an unhealthy grade, I should use the mildest sort of a purgative. Nothing that would nauseate should be given. What we desire is a substance that is at the same time a laxative and a sedative. Calomel in small quantities combines both of these qualities. I often use the following formula:—

℞. Calomel, gr. ij
Subnitrate of bismuth, ʒ ss ad ʒ j
or
Bicarbonate of soda, ʒ ss ad ʒ j

This I divide into twelve powders, and give one every two hours until the bowels are moved or all the powders have been taken. If there is much irritation of the stomach I use bismuth, but if the stomach is quiet, I use soda. If you produce one comfortable stool, you have done enough, and there is no longer any justification or necessity for purgatives. If, after using a dozen of these powders no stool is produced I should stop them and would use the ordinary liquid citrate of magnesia in very small doses. To an adult I should give f ʒ ij every two hours until a stool was produced; or, I should give one-third or one half of a seidlitz powder.

In all of this class of cases, you will find that laxatives act with unusual force. After this woman came in she had two or three loose stools, but no sooner was she put upon a soothing treatment and simple diet, than the bowels became quiet and remained quiet, and on the ninth day the fever was gone.

You have a patient who is about to have typhoid fever, and you give him an ounce of oil, or a couple of compound rhubarb or compound cathartic pills, and that man has eight or ten loose stools, and you so far aggravate the disease of the bowel, that you may have converted what would have been a mild case into a severe one.

You have a patient with catarrhal irritation, and you give him strong purgative doses; you fix that inflammation in his bowels for fourteen or fifteen days—five or six days longer than it need have been, because you aggravate the lesion in its very inception. If you had a patient with a simple fracture, and the indication was to secure primary union, and you took hold of the bones and produced active crepitus for twenty minutes, the treatment would be about as philosophical as it is to give active purgatives in these catarrhal conditions. I earnestly hope, as one result of our studies, that we shall come to a definite conclusion not to use purgatives in acute diseases, unless they are absolutely called for, and that when they are necessary, we shall give some mild, sedative laxative, in minute doses, oft repeated.

There can be no question as to the serious harm that has resulted from the excessive use of purgatives in acute disease. The success of homœopathy has resulted largely from this practice on the part of physicians, and there is nothing which continues to do more harm than an adherence to it.

Relapse in Typhoid Fever.

I want to again call your attention to this typhoid fever case. He has had a relapse. His temperature when you saw him last, the 13th, was only 100.4°; his pulse rate was 88 and respirations 20. On the morning of the 14th he was just as well, but in the afternoon his pulse began to go up; the temperature jumped at once to 104°; the morning of the 15th it was 102°, in the evening 104°; morning of the 16th 102°; last night 104°; and this morning it is again 102°. After there had been a great reduction of the morbid process, there is a very abrupt and severe renewal of it. Of course, this is associated with a renewal of one of two things; either more poison

has entered his blood, or else there is an outbreak of some local irritation.

What symptoms has he presented? He became delirious, but his delirium was of a very mild type until last night, when, I am sorry to say, he quietly got out of bed and walked some distance, but he does not seem to have hurt himself. His tongue is moist and slightly coated. Examining his chest, I find the heart sounds normal. He has not had much cough. The chest is resonant throughout. There are a few bronchial râles. There is no reason to suspect any definite pulmonary trouble. There is merely congestion and bronchial irritation. He has had two small attacks of epistaxis. The bowels are quiet. We must, therefore, attribute this local outbreak and sudden rise in temperature to the beginning of disease in another group of follicies and glands of the bowel. I have no doubt that the epistaxis was due to enlargement and ulceration of follicles in the nose.

This man is in for another little siege. A fresh group of glands have become inflamed, and this must run its course. We have not nearly reached the point where we can relax the rigidity of our treatment in this case. More than this, knowing that the separation of the sloughs from a former group of ulcers was followed by a hemorrhage of almost a pint, we have great reason to fear another sudden burst of hemorrhage, and this, in his present weak condition, would, of course, be more serious.

Under these circumstances, I think it proper to add stimulus in moderate amount to the treatment of this man. I want to call attention to the gratifying fact, that while the temperature has gone up so high the pulse rate has remained excellent; it has not reached 96 per minute since the evening of the 14th. I told you when we had this man before us last, that he had a markedly dicrotic pulse; to-day it is less so. I shall, therefore, give stimulus in only small amounts. We shall give him f℥ iij of sherry wine every twenty-four hours, in the form of wine whey, made into about twelve or fifteen ounces of whey. We shall give him a wineglassful, alternately with his milk. The pills of nitrate of silver and opium will be continued, but I shall increase the frequency of administration, hoping to favorably influence the diseased glands.

His temperature has now reached a point where it may be questionable whether it is not right that something more positive should be done for its reduction. It has reached a point where a good many authors would say that the patient should be put in a cold bath, and kept there until the temperature goes down. I never for one moment assent to any such practice. I should advise sponging with tepid water at a temperature of 72° and containing a little vinegar and carbolic acid, or a little alcohol and carbolic acid. That will reduce the temperature. I do not care about bringing it down too rapidly. It is not associated with grave nervous and cardiac symptoms. It is due, I think, to the local trouble. If his temperature remained persistently at 104°, I should certainly adopt stronger measures for its reduction; but as long as there is this marked fall of two degrees in the temperature every day, I do not think it necessary to resort to a treatment so disturbing as cold water bathing.

I hope that we may be able to avert the great danger here, which is hemorrhage.

Periscope.

The Victims of the Ring Theatre, in Vienna.

The *Allgemeine Medicinische Central-Zeitung* publishes Professor Hoffmann's report on the methods adopted for the identification of the victims of this great fire. Some of his observations will no doubt be of interest to our readers. In this report he says: Over two hundred and fifty bodies were examined, and a great many among them identified. In many cases, owing to almost complete carbonization, sex could only be ascertained by internal examination; the presence or absence of the uterus and ovaries being our only guidance. Age could likewise only be approximated, yet was of importance in establishing identity. Simple inspection often revealed strange transformations: age bore the semblance of youth, and reciprocally. In such cases we had to rely on the indications furnished by the humerus, with regard to complete union between the diaphysis and epiphysis. As you are aware, this only becomes perfect after the twenty-fourth year. In like manner, the ossification of the ribs and larynx served as indices; for you remember, with this last it commences at from thirty to thirty-five, and is complete by about the fortieth year. The condition of the ovaries supplied valuable information. In girls and young women they were quite smooth, but in older subjects they had that well-known uneven appearance which they assume after numerous ovulations.

The hair and beard on a great many bodies had become of a uniform black color, and only by careful cleansing were they restored to their natural hue.

The color of the eyes was not easily detected, the cornea having a milky and cooked-like appearance. In some cases an opalescence of the iris led us to believe the eyes were blue.

The teeth were calcined, and so brittle that they crumbled under the least touch. They looked as if carious, and it was often very difficult to judge of age from the amount of wear they presented. We found great quantities of artificial teeth.

When the hands were under inspection the condition of the epidermis and finger nails supplied indications. In proof of this, let me tell you an episode. An aged couple and their son were in search of a young woman, the wife and daughter. As an indication, they said her finger nails were red, from nursing. A body was found with breasts and nails answering this description, but around the neck was an "amulet" and cross, and the sorrowing family were Jews. Later, however, another body was discovered, and fully identified by them.

Under the head of "particular marks," we noticed a cicatrix from coxalgia, and a cyst at the root of a right index finger. Of course, we found many hernias and hernial bandages.

In all, we ascertained six cases of pregnancy, of which one was in the sixth month, two in the second, and two in the third. In one of these last, all that remained was the neck, the uterus and ovaries having been carbonized. The breasts contained some colostrum. This body was identified.

Surfaces still covered by portions of clothing were found well preserved, even upon bodies otherwise greatly carbonized.

As may well be imagined, we met with burns of every degree, but generally speaking, only very few bodies bore the appearance of having been burned while alive; external erythema and phlyctænæ being quite rare. It is probable that the majority of the victims in this terrible catastrophe were first smothered by smoke, and only burned while in asphyxia, in agony, or after death.

In some cases skulls had been carbonized and split open by the heat, exposing the calcined brains; and many abdomens were found gaping open, their shriveled contents having remained undisturbed.

Remarkable Case of Periodical Peeling of the Cuticle.

A. Chevallier Preston, M.R.C.S., reports the following singular case in the *Lancet*:—

M. J., aged sixty-seven, a fairly nourished woman, of fair complexion, came under my care in July last. The complaint from which she was then suffering was of old standing; but she stated that she had, with this exception, enjoyed good health from childhood. The only serious illness had been smallpox at the age of two years, and she has a large bronchocele, which developed at the age of puberty. Subjoined is the history she gave me of her present illness, which is, according to her statement, identical with what she has suffered at intervals since childhood. At intervals of a month or six weeks the following occurrences manifest themselves: After a day or two of slight feeling of malaise, the skin of every part of the body comes away in "casts," and the cuticle, which separates from the extremities, does so in one entire and sometimes unbroken piece, resembling a "glove" or "stocking." The new skin beneath has the appearance of ordinary skin after desquamation, and "lasts her," to use her own expression, for several weeks, when it begins to get irritable and inflamed. She has lately been going through one of these "changes," and I have had the opportunity of watching her daily. The first time I saw her, a week before the final "casting off," she was feeling unwell, and told me she was expecting a change of skin, and begged me to give her no medicine, as she had found that certain medicines that were prescribed for her at this stage made the skin fall off more thickly, and caused her pain, by leaving only a thin covering all over the body; at least, this was her experience. She was then suffering from slight rheumatic pains in her left elbow, for which I prescribed an anodyne liniment, which relieved her; but she was not able to continue it, as the peeling commenced where the liniment was applied, and the new skin was too tender to bear it. She was kept in bed, being cold weather, and in three days the desquamation became general, the skin of her nose, ears and hands coming off as complete casts. The desquamated skin is of the thickness of the ordinary cuticle, and in places it is as tough as the lining of a hen's egg. I have preserved the covering of the hands and feet in spirit. Now that the skin has come off she expresses herself as "quite well" again, and is able to get about, feeling far more comfortable in the new skin than in the old one. I questioned her closely as to her previous history, and could gather nothing from it to throw any light on the cause of this extraordinary phenomenon. She has had a large family, and has healthy children; none of them having any appearance of her idiosyncrasy. The state of her menstrual functions was always good up to the change of life, seventeen years ago; and she did not associate this occurrence with the menstrual flow at any time, unless by accident. She states that she first remembers an attack of this kind at the age of seven years, and she was afterwards told by a medical man that it was from "catching cold after the smallpox." The phenomena of this disease are so unfamiliar to me, that I shall welcome any hints as to diagnosis, etiology and treatment of the case.

Inoculation for Pannus.

In the *American Practitioner*, Dr. W. Cheatham, after describing the different varieties, and discussing the etiology of pannus, says, "Many remedies have been advised. Argenti nit., cupri sulph., acid tannic., and poultices, besides operative procedures, are a few only of the corrective measures recommended. These may give some relief in the milder cases, but where you have a true pannus crassus to deal with, I do not believe that anything will yield the result that inoculation with blennorrhœal matter will." He then relates the following case:—

"A farmer, aged forty, general health not very good, came to see me in September last, about his eyes. I found him with one of the worst cases of pannus I had ever seen. The corneæ were so thoroughly vascular that the pupils could scarcely be seen. He was unable to see more than to tell daylight from darkness, or white bodies. The palpebral conjunctivæ were thickened. After some weeks' treatment of lid they were greatly changed for the better. No treat-

ment to corneæ improved them any. He was also on general treatment at the same time.

"Finally, giving up all hopes of relief from the usual course, I told him frankly there was but one thing else I could advise with any prospect of relief. I stated the case to him plainly, telling him I would inoculate his eyes with pure gonorrhœal matter; stated the pain he would suffer, the chances of ulceration and atrophy of the globe. I everted both upper lids and applied it thoroughly to them. In about three days the lids were swollen and œdematous, with some discharge from eyes. In a week the disease was well developed. I did not undertake to control it for about ten days. Then I used iced cloths locally, with a collyrium of tannic acid grs. xx to aqua dest. ℥ j, dropped into eyes three or four times a day. In using this I usually direct that the eyes be thoroughly cleansed with cool water first; then the medicine dropped in; in a few minutes the eyes cleansed again, and the application repeated. Between these applications the eyes were thoroughly cleansed every hour or two. This prevented any increase of trouble and appeared to decrease amount of discharge some. After using this for ten days I ordered a collyrium of argent. nit. gr. j to aquæ dest. ℥ j to be dropped into the eyes every two hours; the iced cloths to be continued. Under this line of treatment discharge almost stopped in a week. I sent him to the country to remain three weeks. He returned a short time ago revealing remarkable improvement. The corneæ were very clear. Vision equal to $\frac{10}{200}$. He said he had no difficulty in going alone anywhere he wished. I should have said while in the country he continued the argent. nit. drops, and will add that there is not now nor will there be any staining of tissues from the use of the nitrate of silver. Five minutes after dropping the medicine in he usually bathed the eyes well in a weak solution of salt water. His sight is still improving."

In conclusion, he believes this to be the *only remedy* for pannus crassus; gonorrhœal matter, or the discharge from purulent ophthalmia or from ophthalmia neonatorum can be used. Whatever the source, be sure it is pure.

Surgical Instruments in the Time of Galen, A. D. 259--268.

We make the following extracts from an interesting article published by Dr. Mook, in *L' Union Médicale*, on a number of surgical instruments belonging to the Third century, and found in excavations made in the Quartier St. Marcel, Paris, in October, 1880. All these articles were contained in a round bronze vessel, in which two buckles and seventy-five coins were found. The cutting instruments are represented by two double-edged knives with blades 2.5 inches long, and light hexagonal handles of same length, the whole made out of one piece. Another instrument of similar form, but with blunt edges, must have served the purpose of a spatula. Still another, may have been used as a spatula, but it differs greatly from the above; its blade is 0.40 inch wide by 2 inches long, with a thin, round handle 0.04 inch thick, by 2.80 inches long, having at its end an olive-shaped ball 0.40 inch by 0.16 inch thick. The use of this is not very clear, it may have served as a probe, or even as a small cautery. Forceps are well represented. They are cut from a single piece of bronze, are beautifully finished, and have lost nothing of their elasticity. Two are pointed, and it would seem, were intended for the extraction of foreign substances, or fragments of bone. Two others, respectively 5.6 and 4.8 inches long, have flat jaws, curved inwardly toward each other, and 0.20 inch wide. A number of serrated forceps affect different forms. Some resemble the two preceding ones, while others have one of their jaws curved at a sharp angle from the axis of the forceps; the serrations correspond exactly, and are models of fine workmanship. An instrument having the form of a small spatula 1.20 inches wide, is adapted to a tubular handle 7.20 inches long, and was evidently used as an insufflator, for the purpose of introducing remedial agents into natural cavities.

The use and preparation of ointments must have held an important place in the medical practice of those days. Five gilt bronze tubes, each six inches long, were used for holding ointments, one still contains some, which has been preserved by the oxide of copper covering its surface.

We must mention a long-handled, half spherical capsule 1.6 inches in diameter, having a beak for pouring out liquids, and used, no doubt, for warming ointments.

We must also notice an instrument so different from any now in use that it is hard to guess its purpose. It is eight inches long, formed of two branches, articulated like scissors, and ending in a curved surface forming the fourth part of the circumference of an ovoid. When closed, this forms a space of about 1.60 of an inch; the handles are ornate, and the articulation nearer to the serrated end. This instrument, when closed, can be safely introduced in cavities, and wounds, and when open, it can grasp bodies, or resect tissues as an *écraseur;* at the same time it may be used as a hæmostat, and for removing detached fragments lodged in its concave surface.

There is also a flat stone, probably used for spreading ointment, and on which to sharpen the different instruments. All these instruments are made of bronze, containing some silver, a fact which has, no doubt, contributed to their excellent preservation.

The Alkaloids Derived from Protein Compounds.

The *Revue Médicale*, in noticing a paper recently published by A. Gautier on the above subject, remarks that in 1872, while investigating the reciprocal transformations of albuminoids, Gautier discovered that when fibrin from blood is allowed to putrefy under water, it becomes liquid, yields albumen, butyric and acetic acids, leucin, tyrosin, and leucein in large quantities, and besides these small quantities of fixed and volatile alkaloids.

Selmi also called attention to the fact that in the cadavers of persons who have died a natural death, the stomachs are found to contain compound substances showing the same reactions as

certain vegetable alkaloids, without, however, preserving their toxic qualities. These substances are not creatin, creatinin, or tyrosin, but are similar to those found in the alcohol used for preserving anatomical specimens. Selmi gave those alkaloids the name of ptomaïns, without, however, indicating how they were formed.

This was reviving Panum's sepoin, that fixed poison of purulent sores, comparable in its activity to the venom of serpents, or to curara or the vegetable alkaloids.

Now, according to Gautier, among the fixed and volatile alkaloids of cadaveric origin, some are inactive, while others, especially the fixed bases, are very venomous. The ptomaïns usually found in the visceræ of recently deceased individuals, generally show different reactions from those produced at a later period.

Among the fixed or volatile bases that are derived from cadaveric substances, there are several which can very readily be mistaken for some of the toxic vegetable alkalies; it is, therefore, highly important to distinguish between them, so as to avoid possible judicial errors, and besides prove the non-identity of those bodies with any of the vegetable alkaloids thus far known. We cannot give here all the details adduced by the author; he thus concludes: Unless in cases where morphine, apomorphine, liquid hyoscyamin, and muscarin are present, the instantaneous production of Prussian blue, in the neutral salt of an alkaloid derived from cadaveric substances, by the addition, first of ferric cyanide of potassium, then of dilute perchloride of iron, is an indication that, very probably, the alkaloid present is one of the ptomaïns.

Alkaloidal substances are likewise formed in the ordinary process of tissue life, while the economy is in its normal state. They occur in variable proportions in bile, urine, and muscular fluid. They are a necessary component of certain very active normal secretions, such as venoms, which derive some of their properties from them. They apparently develop in considerable quantities under certain pathological circumstances, and are one of the causes of those functional troubles which follow in many diseases, especially when there is an exaggerated tendency to disassimilation, and above all, when the elimination of urinary products is obstructed. If our urine in its normal condition contains toxic substances analogous to those found in venom, it was natural to suppose that saliva would also contain them, since it is produced by glands similar to those supplying it in venomous snakes. It has, in fact, been found that human saliva really contains one or more of those substances, and although it differs in activity according to the time when secreted, it has proven itself venomous, at least for birds. It would therefore appear that the venom of snakes differs from human saliva, more in intensity of effect than in actual composition.

A New Solvent for Diphtheritic Membrane.

Dr. W. Hale White thus writes to the *Lancet:* I had been testing for some time the various solvents for diphtheritic membrane, such as lactic acid, etc., recommended in the text-books, and finding them all useless in practice I began to look about for new ones. I accordingly procured a supply of acid glycerine of pepsin, in readiness for any case that might occur. The following are brief notes of the first case that I encountered:

Louisa D., aged two years and a half, was first seen on the morning of July 5th, 1881. There was extreme lividity, sucking in, and dyspnœa. I performed tracheotomy immediately (high operation). Instant relief was afforded, and the back of the trachea was inspected, but no membrane was seen. Accordingly a silver tube was put in, and the child did well till the evening of the 7th, when a small piece of membrane was coughed up. I therefore sprayed the throat with a Siegle's spray, putting half an ounce of the glycerine of pepsin in the glass bottle. This was done every two hours. On the morning of the 8th, as very little spray could be got down the tube, I put in Mr. Golding Bird's dilator (which the child continued to wear till the india-rubber tube was put in) and pulled up several pieces of membrane, and continued the spray. This treatment was continued till the evening of the 10th, when, as no membrane had been coughed up for twelve hours, it was left off. It was the opinion of all who saw the pieces coughed up that they had a very soft and gelatinous character, compared to the thick, tough pieces of membrane usually expelled. The case was a very bad one, as is shown by the fact that the quantity of membrane coughed up was very great, by the temperature rising to 104°, the child suffering from vomiting and diarrhœa, and also by its having a severe attack of syncope, from which it was with difficulty roused. An india-rubber tube was introduced five days after the operation. This was soon left off. The child continued to do well; but unfortunately some time after, owing to sudden changes in the weather, it got broncho-pneumonia, and died. At the post-mortem examination there was no evidence whatever to show that the pepsin had any ill effect at all upon the lungs, bronchial tubes, or trachea.

The pepsin was got to its active temperature by being immersed in water at 110° F. before use. I found that the water coming as spray from the boiler was not hot enough to destroy the activity of the pepsin, and as the child had a steam kettle attached to the tent the air in the trachea did not cool it. Of course the steam kettle was removed during the application of the pepsin. I do not think the chief good was done by the action of the pepsin on the large pieces of membrane lining the trachea and larger bronchi, but by its getting thoroughly mixed with the secretions in the small tubes and preventing the formation of membrane there, for it is always found post-mortem that it is the blocking up of these that has killed, provided the child has died simply from the effects of the membrane, without any complication.

It may be mentioned that any one can convince himself of the power of the glycerine of pepsin to dissolve diphtheritic membrane by putting a piece in a test tube, with some of the fluid, and maintaining it at a temperature of from 100–110° F., when it will be seen to be digested rapidly.

This one case he hopes may induce others to try the remedy and furnish their experience. The preparation used by him contained less gly-

cerine than the usual preparation, so that it might more readily pass through the fine tubes of the Siegle spray.

Reviews and Book Notices

NOTES ON CURRENT MEDICAL LITERATURE.

——*The Medical Register* comes to us as the successor of the *American Specialist.* It will be published monthly, with the design of conveying careful criticisms and reviews of new books, with short articles of interest to the profession.

——We have received the twenty-seventh annual report of the Board of Managers of the Howard Hospital and Infirmary for Incurables.

——The Trance State in Inebriety; its Medico-legal Relations, by T. D. Crothers, M.D., Superintendent Walnut Lodge, Hartford, Connecticut, with an Introduction on the Nature and Character of the Trance State, by George M. Beard, M.D., comes to us in the form of an essay, read before the New York Medico legal Society.

——We have received the second annual report of the Newark Charitable Eye and Ear Infirmary.

——"Observations on the Part the Obstetrical Forceps Plays in the Indication and Prevention of Perineal Lacerations," by Thos. A. Ashby, M.D., comes to us in the form of a reprint from the *Maryland Medical Journal.* Among other conclusions, he states that "the forceps gives the obstetrician perfect control over the head when arrested at the outlet. It may be used advantageously to rotate, extend or retard the movements of the head. By the exercise of this power the head may be made to execute the natural evolutions, and thereby prevent undue injury to the perineum."

——Nervous Shock as a Therapeutical Agent, by Romaine J. Curtiss, M.D., Joliet, Ill., comes to us in the form of a reprint from the St. Louis *Medical and Surgical Journal.* After reciting many illustrative cases, the author expresses his belief that in time it will be recognized that the operations of iridectomy or that for pterygium will have as beneficial an effect upon atrophy of the optic nerve, when they co-exist, as the operation of circumcision has been known to have, when phimosis was co existent with such atrophy.

——*Godey's Lady's Book* for March is full of good things. The steel plate, "The Little Pilferer," tells its own story, and the colored fashion plate is a gem. The novelette is from the pen of Mrs. M. Sheffey Peters, and is one of the very very best of the series of complete novels given in the Lady's Book. The illustrations, stories, etc., are all first-class.

——We have received the Fifth Annual Report of the Managers of the Sanitarium Association of Philadelphia. This is a most worthy organization, whose purpose it is to take the little children of the poor from their crowded homes to an island in the river, where they may inspire pure air. Contributions can be sent to the treasurer, Dr. Eugene Wiley, 330 Reed St., Phila.

BOOK NOTICES.

Percussion Outlines. By E. G. Cutler, M.D., Assistant in Pathological Anatomy, Harvard Medical School, etc. etc., and G. M. Garland, M.D., Assistant in Clinical Medicine, Harvard Medical School, etc. etc. Boston: Houghton, Mifflin & Co. 1882. pp. 75. Price $1.50.

This is a valuable book. The majority of general practitioners are very inferior in physical diagnosis, and among the reasons for this deficiency stands prominently the fact that they are not familiar with the normal outlines of the various organs; hence they are unable to diagnose accurately by percussion any increase or diminution of size. This book will supply to them this requisite knowledge. It contains eleven illustrations, with explanatory texts.

An Index of Surgery, being a Concise Classification of the Main Facts and Theories of Surgery; for the use of Senior Students and others. By C. B. Keetley, F.R.C.S., Senior Assistant Surgeon to the West London Hospital, etc. pp. 208. Price $1.00. New York: Bermingham & Co. 1882.

This book is a cheap compendium. It contains in a very concise and very stilted manner the prime elements of surgical knowledge; to those for whom the author (in his preface) says he intends it, it may be of some service.

The Sanitary Drainage of Houses and Towns. By George E. Waring, Jr. Second Edition, Revised and Enlarged. pp. 366. Boston: Houghton, Mifflin & Co. 1881.

This is a very valuable work for all classes. Physicians will learn much of value from it, while any layman about building a residence should be advised to consult its pages, in order that he may surround himself with all possible barriers against the introduction of disease. Colonel Waring is thoroughly conversant with his subject, which he has here presented in an attractive and entertaining style.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE LEGAL RESPONSIBILITY OF PHYSICIANS

There are very few medical gentlemen who thoroughly realize the importance of some knowledge of the legal responsibilities they may incur in the daily routine of the profession. The *British Medical Journal*, in a recent issue, relates several striking instances of this unsuspected danger. In one case a woman arrested on suspicion of having concealed the birth of a child was examined by the Police Surgeon, to ascertain whether she had recently been confined or not, although she had previously confessed to the birth, and remarked that "*there was no use in examining her.*" She subsequently brought an action for damages against this physician, on the ground of assault; the presiding justice charged the jury in these words: "*Before the examination took place she admitted having had a child; the jury must ask themselves, if that admission was made, why examine further; there was no legal authority whatever to examine this girl.*" After a short absence the jury returned a verdict of one hundred and twenty-five dollars damages for the plaintiff. Some years ago one of our most prominent surgeons in this city was called upon to attend a fracture of the femur. The bone was set and the limb placed in proper position, while careful instructions were given for future management, and absolute rest enjoined. The latter injunction was disobeyed, erysipelas supervened, and shortening of the leg was the result. A suit for damages followed, and while the surgeon was successful, yet he was forced to much undeserved expense and annoyance. Many such cases are reported and could be cited to point our position. We must ever remember that there are many unprincipled persons in the world, and also anxious, eager, vulture-like lawyers, ever ready to whisper into the ear of a willing client, "Sue him for damages; he has money; he has treated you badly, make him pay for it;" and there are many ready and willing to listen to this evil advice. Some of the English courts hold that whenever a physician makes an examination of a woman without having her clearly expressed consent he is guilty of *assault*. She may not *resist*, they claim, because there may be, to her knowledge, some collateral circumstances capable of forcing her acquiescence if she does refuse; though these fears may not be well grounded, yet if they seem to her sufficient to make resistance, to her mind, useless, then such an unwilling examination constitutes assault. They even decided, as far back as 1824, "*That if a medical man unnecessarily strip a female patient, under the pretence that he cannot otherwise judge of her illness, it is an assault,* IF HE HIMSELF TAKES OFF HER CLOTHES.

These decisions are all eminently just and proper. Morality is one of the greatest foundation stones of social prosperity, and must be most zealously guarded. The purity and privacy of the female must be rigidly maintained, if morality is to be encouraged, and this barrier which must ever surround the modesty of women can only be passed when the absolute necessities of deranged health imperatively demand it, and then exposure must only be carried to such a degree as is indispensably necessary. These decisions are based on the *unnecessary* exposure of the female, and are, therefore, just.

Since there are many women who are ready to be induced to bring suit against physicians on the slightest provocation, or even, indeed, with out any just cause at all, it, therefore, will be a wise precaution to bear ever in mind the fact that it has been decided that examination without express consent constitutes assault.

To avoid this pitfall, in which many have and many more will innocently find themselves, unless they heed this caution; it should be made a rule to previously obtain full and free consent from a woman, before a witness or witnesses, ere you undertake an examination, and to surround yourself with the additional safeguard of a witness during the operation. The relations sometimes existing between physician and patient are of an extremely delicate nature, and unless carefully and cautiously conducted, may, in certain instances, redound greatly to the detriment of the physician.

NEW REMEDIES.

In this age of medical progress, new medicinal remedies are being constantly brought before the profession. It is hardly possible to pick up a good medical journal without meeting an account of some hitherto unheard-of drug which is reputed to be of great service in the cure of some particular diseased conditions. In truth, to such an extent has this introduction of new drugs been carried that a journal appears in New York devoted to the chronicling of their advent into public notice. The majority of them are subsequently found to be worthless or even worse, to be really injurious, and are discarded. We have now, and have had, certain good, reliable friends in the materia medica, that have done good service for our fathers and our grandfathers before us, and are still potent for good; such as opium, quinine, digitalis, strychnia and the like. Of the new remedies, with the exception of such really valuable additions as jaborandi and a few others, they live a short time and pass away, forgotten and unmourned, because they possessed merit only in the imagination of their introducers.

We do not desire to advocate *old fogyism;* far from it; we are champions of progressive medicine; but in our science, as well as in every other human pursuit, a rational amount of conservatism is commendable. We must receive with a good many grains of salt the glowing accounts of wonderful cures by unheard of drugs that so often attract in the journals. The majority of medical men are ambitious to discover some new drug more potent than any in use. Hence, when they have used such a remedy in, maybe, but a single case with a successful result, they do not stop to consider whether this patient might not have recovered if let absolutely alone, but straightway rush into print with what they consider a great discovery. Therefore would it be better for physicians to put their trust in well tried remedies, and not to *experiment* with all the new ones they hear about, until their merits have been absolutely proven.

THE DANGERS OF CATHETERISM.

A recently reported case in London, where death occurred as a result of the passage of a catheter, furnishes a lesson for all to remember. It is well known that the introduction of this instrument, even in those of sound and vigorous constitution, has, in not a few cases, been followed by severe rigors and death. Why this should be so is not positively demonstrated, though it would be rational to suppose that its action was due to the impression made on the nervous structure of the sexual organs, and transmitted from there to the vital nervous centres. The nature of the impression we know not; but we do know how to avoid it, and this, after all, is the important practical point. In the London case, after the introduction of the instrument, the man was allowed to walk away and do as he chose. He was soon after taken with severe urethral hemorrhage, which had occurred in a slight degree at the time of the operation, and died in three days. To avoid these accidents, the following rules should invariably be observed, else, if you neglect them, you may, knowingly, be the cause of severe trouble, and maybe death.

1. Place the patient in bed, *between blankets.*
2. Warm the catheter to such a degree (by dip-

ping it in hot water or other means) that it will feel warm, *not hot*, to the back of your hand. 3. Oil it well and introduce *without using the slightest force;* if you do use force, you will be very apt to lacerate the urethra, and possibly to produce a false passage, with all its subsequent horrors. 4. Keep the patient in bed, between the blankets, for at least an hour after all the nervous excitement caused by the operation has subsided, and give him a big dose of quinine, from five to ten grains. By observing these simple precautions you will almost never have any resultant trouble from the passage of a catheter in a healthy man.

VIVISECTION.

In a recent issue, the London *Medical Times and Gazette* criticises an article in the "*Fortnightly Review*," from the pen of the famous Lord Coleridge, against vivisection. There always have and always will be two parties to this question. The subject has been thoroughly discussed, and yet stands to-day as it did in the beginning. What is the use of wasting time and mental force on these elaborate arguments concerning the justice or morality of vivisection. The practical point that must stare in the face of all, whether they favor or oppose it, is, that it will continue to be, in spite of all the anathemas hurled against it. So long as man exists, so long will there be found enthusiastic students of physiology, and by them vivisection *will* be practiced, whether sanctioned or not, since they deem it necessary to the pursuit of their studies. Dissection of dead human bodies is forbidden in some places, with the result that graveyards are robbed and dissection goes on all the same. So with vivisection; it ever will be a fact, openly, or secretly; why, then, waste time writing or talking about it?

Notes and Comments.

Linear Scarifications in Lupus.

This method of treatment, which has received special attention in England, from Balmanno Squire, and in France, from M. Vidal, of the St. Louis Hospital, has already rendered the greatest service in this terrible disease.

This method was first brought forward by Balmanno Squire, but has been much simplified by M. Vidal, who immediately commences the treatment by scarifications without preliminary cauterization with chloride of zinc. M. Vidal uses a very narrow, sharp knife, and makes long, superficial linear incisions over the whole of the affected surface; the incisions are made very close together, and there is considerable effusion of blood, which is, however, very soon arrested.

We have very frequently seen the little operation performed by M. Vidal, and it caused considerable pain at the moment, but not of long duration. The results obtained were often excellent, the cicatrices smooth, without induration, and often hardly perceptible.

In his "Leçons sur le lupus" (Paris, 1879), M. Vidal says that this treatment is excellent in tuberculous lupus and in lupus of mucous surfaces, but does not give as good results in the erythematous form, and particularly in the acneiform variety, of the disease.

This mode of treatment is very much used by the physicians of the St. Louis Hospital, and, according to MM. Lailler and Besnier, gives better results than the modifications of the method proposed by Dubini and Schiff, who recommend introduction of minute quantities of caustic substances into each tubercle by acupuncture.

The Treatment of Whooping Cough.

In the *Allegemeine Med. Cent.-Zeitung*, Dr. Elben says that he has treated whooping cough in a great many ways: he has tried inhalations of tannin, quinine internally, and insufflations of quinine and bicarbonate of soda. He then returned to belladonna, chloral and morphine. In particularly serious cases, in which children were in danger from want of sleep, or owing to vomiting of all food, he has exhibited morphia in bold doses with excellent results; great prudence should of course be observed in using this remedy, and the first symptoms of intoxication must be carefully watched. In some instances bromide of potassium brought relief, but in others it was of no avail.

In three cases Dr. Elben has had occasion to try oxalate of cerium, as recommended by Morgé. To his surprise, he observed such marked progressive improvement, especially in patients suffering from severe attacks of cough and vomiting, that he was induced to suspend all other medication.

In one case he discontinued the cerium and replaced it by morphia; then, finally, all remedies were withheld. In each instance the disease became aggravated, thus warranting the belief that the remedy possessed specific qualities. For children one to seven years old, the dose of powdered oxalate of cerium is from 0.03 to 0.18 grm. (grs. 0.45–2.70), to be taken at one time, and while fasting; later in the evening another similar dose is to be given.

Regeneration of Nerves.

At a recent meeting of the Societé de Biologie (January 21st), M. Brown-Séquard related that, in forcibly elongating the sciatic nerve of a monkey rupture took place. The two ends of the nerve were resected, as far as possible, at the superior and inferior extremities of the wound.

After two months the animal had recovered neither the motility nor sensibility of the muscles under the dependence of the resected nerve; nevertheless, at the autopsy it was found that the nerve had been completely regenerated.

At the superior part of the wound it was continuous with the primitive nerve, and below, without apparent demarcation, with the popliteal branches.

The new nerve, it is true, had not recovered all its connections with the medulla, but its complete reparation in so short a space of time was truly remarkable.

Treatment of Pigmented Spots on the Skin.

Dr. Unna, of Hamburg, recommends the application of simple mercurial plaster, or a plaster made with white precipitate over the colored spots. The skin is first sponged off with Cologne water, or alcohol, and then the plaster in narrow strips is applied, and left on during the night. During the day the following pomade, innocuous to the skin, and much used as a face application by the high society of Vienna, is recommended in the *Berlin. Klin. Wochenschr.*:—

℞.	Bismuth. subnit.,	ʒ iss
	Kaolin,	ʒ iss
	Vaselinæ,	ʒ vj to ℥ iss. M.

This preparation is applied over the affected parts, and, in conjunction with mercurial plaster, effects a rapid cure.

Alveolar Osteo-periostitis in Diabetes.

The *Concours Médical*, for January 14th, 1882, observes: Diabetes was again the subject under discussion at the last sitting of the Academy, and M. Magitot presented the results of his labors on the "Diagnostic Value of Alveolar Periostitis of the Jaws in Diabetes Mellitus." His conclusions were as follows: 1st. An examination of the mouth will invariably furnish a sign for the diagnosis of diabetes mellitus. 2d. This sign is a lesion of the alveolar edge, known under the name of alveolar osteo-periostitis. 3d. This indication of diabetes, which appears in the first stages of the disease, continues throughout its duration, and under certain circumstances, acquires all the importance of a revealing sign. 4th. A simple deviation of the teeth serves as the first indication of diabetes. The second period in the disease, when it has become general, is marked by loosening of the teeth and alveolar catarrh. The third period, that is, when the teeth drop, corresponds with the most advanced stage of the disease. 5th. Beyond this last period, if diabetes continues its evolution, the alveolar edges may become the seat of an osseous reabsorption, either consecutive or not to gingival gangrene.

This last indication is a critical one, and as a rule, closely precedes a fatal termination of diabetes.

Salicylic Cream.

Dr. Matthews Duncan recommends, in the *Lancet*, salicylic cream, prepared by mixing one part of the powdered acid with four or five of glycerine, as a valuable means of keeping sponges, tents, instruments, etc., aseptic in the vagina. It had been suggested to him by Dr. Alexander Ogston, of Aberdeen, and he had used it with success in inducing premature labor, and other operations.

Rheumatism as a Cause of Purulent Conjunctivitis.

Blennorrhagia has been generally considered as a cause of purulent conjunctivitis, but M. Perrin has had occasion to observe a number of cases in which surrounding circumstances precluded the possibility of blennorrhagic infection, but distinctly pointed to rheumatism as the determining cause. The *Concours Médical*, from which we quote, adds, that M. Perrin, in submitting the results of his observations to the Academy, said that rheumatism of itself could determine urethral discharges similar to those from blennorrhagia, and which, in such cases, would be an effect, instead of a cause. He was, therefore, inclined to believe that urethral, ocular, and other symptoms might be superinduced by a rheumatismal condition, developed by various circumstances, and attended by simultaneous, or successive manifestations, but which,

according to individual predisposition, would become localized in the conjunctiva, the urethra, or often in the articular system. In commenting on this question, M. Gosselin remarked that he had never observed anything similar to the facts reported by M. Perrin; he availed himself of the circumstance, however, to call attention to the good effects of dilute alcoholic lotions (dilutions of one-fourth or one-fifth), in the treatment of purulent conjunctivitis.

Local Treatment of Aphthous Stomatitis.

A late issue of the *Therapeutique Contemporaine* gives various formulæ which have proved useful in these obstinate diseases of the mouth.

The antiseptic gargle of the Brompton Hospital has often proven of great service; it consists of—

℞.	Aluminis,	gr. xvj	
	Tr. myrrhæ,	ʒ iss	
	Aquæ destil.,	ʒ iv.	M.

This may be used to touch the aphthæ, and also as a gargle.

If the disease proves obstinate, and no beneficial effect is obtained from the above mixture, Tommasi recommends the following powder:—

℞.	Calomel.,	ʒ ss	
	Amyli pur.,	ʒ ss.	M.

Apply a small quantity of this over the surface of the aphthæ.

Thompson recommends in the same conditions the following composition:—

℞.	Tr. opii,	♏xlv	
	Tr. catechu,	ʒ iiss	
	Ac. sulphuric. dil.,	♏xlv	
	Aq. rosæ, ad	ʒ vss.	M.

The points affected should be touched with a camel-hair pencil saturated with this mixture.

Cause, Nature and Treatment of Yellow Fever.

Dr. Domingos Freire has published (Rio Janeiro, 1881) a monograph bearing the above title.

As he found in the dejections, the saliva, and the blood of yellow fever patients, numbers of microscopic organisms, bacteriæ and cryptococci, he comes to the conclusion that the disease is of an infectious nature. And as the salicylate of soda had been much recommended in analogous affections, such as septicæmia, variola and typhoid fever, he determined to investigate its effects in yellow fever.

He had administered the medicament hypodermically, in doses from 2½ to 22 grains, according to the intensity of the fever, in the first period of the malady. In the second period, the dose should be smaller, as it then acts as an antiseptic; it is of no service in the third period, when black vomiting has commenced.

Dr. Freire reports several cases with favorable issue under this treatment.

Hypertrophy of the Heart in Bright's Disease.

In a recent communication to the Soc. de Biologie, M. Straus gave the results of clinical and experimental researches which he had undertaken, to determine the relations existing between renal lesions, whatever their origin, and cardiac hypertrophy.

The existence of such hypertrophy has been admitted without contest since the days of Bright and Traube, and the troubles in the renal circulation were considered sufficient to explain a compensatory hypertrophy of the left heart. More recently, Gull and Sutton have considered that the elevation in arterial pressure and the consequent cardiac hypertrophy was due to a form of generalized arterio-sclerosis affecting all the peripheric arterioles.

Finally MM. Debove and Letulle have described a species of hypertrophic myocarditis with sclerosis, in Bright's disease, which would seem in some cases to exist primarily and have no connection with atrophy of the kidneys.

M. Straus sought, in his experiments, to provoke nephritis in one kidney of the animal operated upon, examining, a considerable period later, the condition of the heart. He has been preceded in this species of research by Bettmann (1858), by Simon in 1871, and more recently, by Gravitz and Israël; in many cases these observers found cardiac hypertrophy without alteration in the second kidney, while in many of the full grown rabbits the other kidney was enlarged, without cardiac alteration.

M. Straus tied the left ureter in twenty guinea-pigs, and with proper antiseptic precautions recovery was in all cases rapid. On examination, a considerable period later, there was considerable distention of the ureter and the pelvis of the kidney, with atrophy of the organ itself; the weight of the second kidney was twice that of the organ in the normal condition.

There was manifest hypertrophy of the left ventricle of the heart, which was demonstrated by weighing, the organ being about one-fourth heavier than normal.

From these experiments, M. Straus considers it decisively proven, that in Bright's disease the cardiac hypertrophy is due or has its origin in the renal disease, and certain cases observed in practice confirm these results of experimentation.

In two cases of uterine cancer, with compression of the ureter, hypertrophy of the heart supervened, notwithstanding the cachectic state of the patients. The heart weighing in one case ten and in the other eleven ounces.

Chloroform in Cholera.

M. Desprez gives, in the *Bulletin de Thérapeutique*, a treatment recommended by him in 1857, and which was found very useful in the terrible epidemic at Damas, in 1875, and in India, in 1876 and 1877, the following potion constituting the basis of the treatment:—

℞.	Chloroform.,	♏xv
	Alcohol.,	f℥ ij
	Ammoniæ acetat.,	℥ iiss
	Syr. morphiæ chlorhydrat.,	f℥ j–℥ ij
	Aquæ,	f℥ iiiss. M.

Sig.—Teaspoonful every half hour.

Chloroform thus administered seems to act on the spasms and contractions of the stomach.

Liquids introduced in very small quantities are no longer vomited, the medicament favors absorption, and as it is very rapidly eliminated, accumulation of action need not be feared.

Without insisting on the theoretic part of the treatment recommended in M. Despres' memoir, it must be said that M. Follet, who followed out the treatment at Pondicherry, had a mortality of but 29 per cent., while under other methods of treatment the mortality reached as high as 80 per cent.

This method of treatment is applicable only during the first period of cholera; as soon as the period of reaction sets in the employment of stimulants and narcotics is of more doubtful benefit, and treatment should be modified according to the symptoms and indications.

Smallpox Disinfectants.

From the *National Board of Health Bulletin* we note the following methods for smallpox disinfection, ordered by the Illinois State Board of Health. The best disinfectants are, sunlight, fresh air, soap and water, thorough cleanliness, for general use. For special purposes the following are the most efficient, the simplest and the cheapest: 1. *Copperas disinfectant.*—Sulphate of iron (copperas), one and one-half pounds; water, one gallon. A convenient way to prepare this is to suspend a basket containing about sixty pounds of copperas in a barrel of water. The solution should be frequently and liberally used in cellars, privies, water closets, gutters, sewers, cesspools, yards, stables, etc. 2. *Sulphur disinfectant.*—Roll sulphur (brimstone), two pounds, to a room ten feet square, and in the same proportion for larger rooms. When using this, have all windows, fire-places, flues, keyholes, doors, and other openings, securely closed by strips or sheets of paper pasted over them. Then place on the hearth, or stove, or on bricks set in a wash tub containing an inch or so of water, an iron vessel containing live coals, upon which throw the sulphur. All articles that cannot be burned, on account of their value, must be left in the room, while this fumigation must last for twenty-four hours, and may be repeated, when the doors and windows should be left wide open for two or three weeks. 3. *Zinc disinfectant.*—Sulphate of zinc (white vitriol), one and one-half pounds; common salt, three-quarters of a pound; water, six gallons. Into this solution all clothing, blankets, sheets, towels, etc., used about the patient should be dropped immediately after use, and should be well boiled as soon as practicable. Into this solution ought to be dipped the outer wrap of any visitor when he leaves the room. In the event of death, the body should be wrapped in a sheet thoroughly saturated with this solution. 4. *Thymol water.*—Made by adding one teaspoonful of spirits of thymol to a half gallon of water. Spirits of thymol is composed of thymol, one ounce, alcohol, 85 per cent., three ounces. This may be used for the same disinfecting purposes as carbolic acid; it is quite as efficient and has an agreeable odor. When thymol is not available, chloride of zinc solution may be used, half an ounce of chloride of zinc to one gallon of water.

Contagious Pneumonia.

In our issue of February 11th we presented a note on *Contagious Pneumonia;* in continuation, we find some fresh information on the subject from the *Lancet*, in which Dr. Frederick H. Daly says: "I do not mean by *contagious pneumonia*, septic, epidemic pneumonia; I do not mean a blood poisoning from—say an insanitary state of a house or a neighborhood; nor yet do I mean the so called diphtheritic pneumonia. I desire to discuss whether there exists a variety of pneumonia beginning with rigors and high temperature, and communicable from person to person, as in smallpox, measles, and scarlet fever. He relates several cases to illustrate his argument. He was consulted by a lady about one of five children who had been unwell for several days, with symptoms of fever and incessant cough. A simple diaphoretic mixture was ordered, and in a few days the boy was quite well.

Nine days subsequently he was summoned to see two of the other children, and found them suffering from undoubted pneumonia. These children had been kept in the same room with the first child. Four days after the beginning of their illness (all of which terminated favorably), the mother was taken sick, as well as the youngest child. The mother had a rigor, pulse 126, temperature 104.6°, tongue coated; constantly coughing, but no expectoration, with a violent pain under the left breast. Fine crepitation all over the left chest soon developed and passed rapidly into consolidation, and death ensued. The child taken sick with the mother presented symptoms of pneumonia, but recovered. The grandmother, aged sixty, a remarkably healthy looking woman, came to nurse her daughter. The evening after her daughter's death she was taken suddenly ill, with a well marked rigor, temperature 105.2°. The next morning there was fine crepitation at both bases and great dyspnœa; well-marked pneumonia was diagnosed, and she died six days after her daughter. A careful physical examination of the first case was now made, when the left lung behind gave evidence of recent consolidation, while the history of the child's illness, the sudden improvement from being so ill, the fever, the cough, every symptom, indicated that this was the first case of pneumonia in the house. I do not think there can be any doubt that there had been in this house six cases of pneumonia, two proving fatal, in about a fortnight. There was no reason to suppose that the disease was that variety of pneumonia described as epidemic, and which has been associated with general unsanitary conditions, such as overcrowding and bad ventilation. My cases support the theory that this disease is a specific fever, of which the lung disease is only the local effect. The servants in the house, who were but little in the sick room, escaped the disease." In conclusion, he says, "We know that certain forms of blood-poisoning can produce pneumonia; such as albuminuria, erysipelas, and measles, most probably. I ask is there still another cause of the disease, not generally, if at all, recognized, viz., direct contagion?"

Special Reports.

NO. IV.—ADULTERATIONS.

Adulteration contaminates everything we use. Let an article of food become desirable and valuable, and straightway some rascal is prepared to get up some cheap resemblance to it, by which it can be adulterated, and more money made for the tradesman. Some of these adulterations are positively injurious to health, while the remainder, though harmless, yet are morally wrong, since we are called upon to pay for what we do not receive. When a man buys a pound of sugar, he ought justly to receive a pound of sugar, and it is an act of injustice and a crime if, through the machinations of man, he receives only three quarters of a pound of sugar and a quarter of a pound of some white earth, which, though harmless, does not possess the properties of sugar. It is a species of robbery, and ought to be exposed. During the past year much light has been thrown upon the question, and the crooked ways of those who adulterate have been made more familiar. Therefore, a report of recent developments in this line will be productive of good, by warning you and showing you how to detect adulterated articles. Legislation can do much to effect a reform, but the public can do still more. If every one knew how and would test every article they purchased, the tradesmen would be afraid to sell adulterated goods, when they knew that detection, loss of custom, gossip and subsequent failure would be the result. Too much attention cannot be directed to this point since in many cases it will be the unsuspected cause of undermining the constitution and producing a condition of chronic ill health. In this journal, last September, it was stated that a municipal laboratory had been recently opened in Paris, where anybody can have analyzed, for a small fee, samples of food, drinks, or anything connected with hygiene. Several samples of butter were found to be made with oil or suet, which were easily separated. This brings up the much mooted subject of oleomargarine. It seems to be the present belief of those most capable of judging and expressing an opinion, that while oleomargarine is not exactly identical in composition with good butter, and does not contain the same elements of nutrition, yet its use is admissible, since it is not absolutely injurious. Dr. Cutter, of New York, in the course of an article on butter, says: "To conclude, butter is good nerve food; oleomargarine honestly made may not be unhealthy, but it cannot, in our opinion, take the place of the normal products of the protoplasm of the mammary gland." The *Pacific Medical and Surgical Journal*, says, "From the first we have regarded this product (oleomargarine), as a contribution from clinical science to domestic economy, in the interests of the human family. Were it not for the motives of trade, and the fears of

competition on the part of the dairymen, there would have been but little question on the subject. The case is one of selfishness and prejudice, arrayed against the interests of the people, the poorer classes more particularly. Professor CHANDLER, State Chemist of New York, recently reported that it was superior to low grades of dairy butter; that there is nothing objectionable in the material, and that he sees no necessity for legislation concerning its use." On the other hand, Prof. RICHE, read the official report of a commission appointed to investigate the propriety of substituting artificial for natural butter, in the French insane asylums, before the Académie de Médecine, in which the following conclusions appeared:—

1st. It appears, from three years' experience at St. Anne, at Vaucluse, and at Ville Evrard, that the employés and some patients could not endure this alteration in the usual fare.

2d. The alimentation, and, therefore, the preservation of health of extra-sensitive and very delicate patients would be unfavorably affected. In any case it would be a serious change in the regime of those whose constitutions were already worn out.

3d. Oleomargarine is a manufactured product, and so open to fraud; it is well known that vegetable oils are used. Moreover, experience shows that some time is required for a stomach accustomed to food cooked in fat to become habituated to that dressed in oil, and physiological researches prove that vegetable oils are less easily digested than animal fat.

4th. Fatty substances are only absorbed into the system in the state of emulsion. Chemical practice and culinary experience having shown that oleomargarine does not emulsionize so readily as butter, and that the emulsion of the former is not as stable as that of the latter, it is reasonable to conclude that oleomargarine is not so easily assimilated as butter.

It is therefore proposed that the commission should reply to the Minister that the Academy considered the proposed substitution inexpedient, and this proposition being put to the vote, was unanimously approved.

Last year the Public Health Committee, of New York took up the matter, and investigated it thoroughly. After taking into consideration the French observations, noted above, it was found that there is a very great mass of testimony from various experts in favor of the article in question. Sanitarians, chemists and physiologists all endorse it as a useful, harmless and palatable addition to our food products.

They recognized the possibility that the new butter is not so digestible as the old. This is an argument for its being sold under its own name, but not for any actual restrictions upon its sale or manufacture. There is, perhaps, a future danger in a less careful process of manufacture than now exists.

As establishments increase and competition becomes more active, the scrupulous care now said to be exercised may relax. This, however, would only justify the existence of official inspectors, and not the abolition of the industry.

The dairy interests in our State Legislature are very great, and the question of the food value of oleomargarine may be settled in the interests of this class rather than in that of the people. But it is to be hoped that the State will not interfere any further than to furnish assurance that the article is carefully manufactured, and is not being sold under any other than its own name.

As an evidence that the fear expressed, that adulteration would creep into the manufacture of oleomargarine, was not unfounded, *Gaillard's Medical Journal* tells us that "The success of butter made from beef fat (oleomargarine butter) has led to the use, in Chicago, of pork fat or lard for the same purpose. It has been reported that large quantities of this fraudulent butter have been shipped to England, seriously injuring the market for genuine American butter. The report is disputed by exporters, though it is admitted that sample lots have been sent by New York and Chicago dealers. Obviously, if lard butter is wholesome, and of good flavor, it can be sold on its merits; if bad, it should not be sold at all. In either case its sale as genuine butter would be a fraud and should be prevented."

Thus, then, to sum up, it would seem that there is nothing morally wrong nor physically injurious in the sale and use of oleomargarine; with these two restrictions: 1st. That it be distinctly labeled and sold as such; 2d. That it be sold at a lower price than genuine butter. It really constitutes a benefit to the poorer classes, since it enables them to enjoy a luxury hitherto denied them on account of its expense. Since it is harmless, it is brought down to a question of desire. If poor people, or any other class, desire to use oleomargarine, there is no valid reason why they should not do so; but it is only just that they should know what they are using, and should be able to procure it at a lower price than the more expensive genuine article. If legislation will force these artificial manufacturers to properly label this article of merchandise, the people will force the low price, by refusing to buy it at a high figure. Until this honest labeling becomes compulsory and universal, physicians and others ought to know how to detect the artificial from the genuine butter. Dr. G. C. WITTSTEIN, in an Austrian pharmaceutical jour-

nal, thus explains the simple method of distinguishing them: "Place a small piece of butter on an object glass, spread it out by means of a cover-glass, and observe it under a power of three hundred to four hundred. If it is pure butter, the whole field is filled with extremely fine globules, which are entirely destitute of any approach to crystalline form. If the butter is artificial, or a mixture of both, the field presents numerous angular or acicular particles between the globules. These crystalline particles are derived, no doubt, from the stearine which forms part of the beef-tallow in artificial butter. Lard does not show any such crystalline particles."

Milk and Cream.

At the Paris laboratory, a sample that was exhibited as cream, and which appeared as natural as possible, and of excellent flavor, was found to have been manufactured with the residue of some red dye, mixed up with oil and sulphuric acid, in certain proportions. It is well known to every one that no article of food is so liable to contamination or adulteration, from carelessness or design, as milk. But the belief must only be the more strongly impressed by the recent report of Mr. Earnest Hart, the editor of the *British Medical Journal*, to the London Congress, when from a tabular abstract, made from a study of seventy-one recent epidemics due to infected milk, he made the startling statement that as many as thirty-five hundred cases of typhoid fever, eight hundred of scarlatina, and five hundred of diphtheria, could be directly traced to the drinking of impure milk. Dr. E. F. Brush, of New York, calls attention to the danger of feeding infants with milk taken from a cow only a few days after she has calved. The milk contains *colostrum*, which will produce severe symptoms of cholera infantum. Many dairymen, some through ignorance and others through carelessness, will mix this early milk with that from other cows, which then constitutes a dangerous adulteration. He cites the case of a breeder of fine stock, who allowed his calves to suckle their mothers as soon as they were born. They grew rapidly, were fat and sleek, and excited the admiration of the breeders of the neighborhood. But when warm weather came they all sickened and died. Subsequently he fed the calves artificially for a few days and had no more trouble.

It is hardly necessary to detail the well-known fact that infected milk is one of the principal carriers of the typhoid fever poison; but the following case, which we believe has not yet appeared in print, will be instructive, as it shows more clearly than any we have ever met how extremely sensitive milk is to the influence of poisonous germs. A case of typhoid fever occurred in the house of a neighbor of a dairyman. The dairy was situated several hundred yards from this house. There was no water communication between them. The clothes and bed clothing of the patient were hung out to air. Very soon an epidemic of typhoid fever, commencing in the members of the dairyman's family, who were especially fond of milk, broke out, and was confined to those persons supplied from this particular dairy. Upon investigation, it was demonstrated that the only possible way in which this milk could have become contaminated was by the influence of the wind carrying the disease germs from the infected clothing toward the dairy. Since the presence of disease germs really constitutes adulteration of milk, though we believe, in the majority of cases, unintentionally on the part of the vender, it behooves every one to always remember and realize the readiness with which milk can absorb injurious elements. Since in many cases it is impossible to say how these disease germs may enter the milk, or to determine accurately, even by the most careful analysis, whether or not milk may contain some elements inimical to health, it becomes absolutely imperative that the two following rules should be scrupulously observed on all occasions: 1st. No milk should be allowed to be sold from any dairy in the vicinity of which there may exist any contagious disease; 2d. No milk should be allowed to be sold from cows that are in any way at all out of health. These two conditions can be carried out by the rigid enforcement of the following measure: In addition to the present inspectors of milk, or rather, in place of them, who examine and test the fluid when it has reached its destination, and who are of very little service, since they cannot possibly (because we have no means of doing so) detect the presence of disease germs, the surrounding country from which our large cities derive their milk supply should be divided into districts, with an inspector for each. This man should be a *practical* one, with a thorough knowledge of all the diseases of cows, and the means of recognizing them. It should be his duty to daily inspect the various dairies and ascertain the condition of the cows. By visiting the physicians of the neighborhood, he could find out whether any infectious or contagious disease existed in the vicinity of any dairy, and putting these two inquiries together, he could decide whether the milk supplied by any particular man would be liable to

convey disease. If any particular cow in a herd were found diseased, he could warn the owner to throw this milk away, until he had satisfied himself that the cow was well. If any contagious disease existed in the neighborhood, he could order such precautionary measures as would render the infection of the milk impossible ; but if such were not practicable, he could forbid the milkman to send his fluid to market until such time as the danger was past. Loss of license could be the penalty for non-obedience. By this means, if intelligent and capable inspectors were appointed, and would conscientiously perform their duty, the almost unpreventable contamination of milk would be reduced to the lowest pos sible minimum.

(To be Continued.)

News and Miscellany.

A Step Backward.

In the English House of Commons, on February 7th, notices were given of the intended introduction of the following bills: 1. Abolishing the compulsory clauses of the vaccination acts; 2. For the total abolition of vivisection ; 3. For the repeal of the Contagious Diseases Act.

Half Knowledge.

The American Practitioner says: "Our American atmosphere is vocal with the flippant loquacity of half knowledge. We must accept whatever good can be got out of it, and keep it under, as we do sorrell, and mullein, and witch-grass, by enriching the soil and sowing good seed in plenty; by good teaching and good books, rather than by wasting our time in talking against it. Half knowledge dreads nothing but whole knowledge."

A Narrow-minded Physician.

Dr. Oliver Wendell Holmes says: "I have known a practitioner—perhaps more than one—who was as much under the dominant influence of the last article he had read in his favorite medical journal, as a milliner under the sway of the last fashion plate. The difference between green and seasoned knowledge is very great, and such practitioners never hold long enough to any of their knowledge to have it get seasoned."

The America of the Future.

The same facile writer says: "As the wine of old vintages is gently decanted out of its cobwebbed bottles,with their rotten corks, into clean, new receptacles, so the wealth of the new world is quietly emptying many of the libraries and galleries of the old world into its newly formed collections and newly raised edifices. No Englishman will be offended if I say that before the New Zealander takes his stand on a broken arch of London Bridge, to sketch the ruins of St. Paul's, in the midst of a vast solitude, the treasures of the British Museum will have found a new shelter in the halls of New York or Boston. No Catholic will think hardly of my saying that before the Coliseum falls, and with it the imperial city, whose doom prophecy has linked with that of the almost eternal amphitheatre, the bronzes, the paintings, the marble, the manuscripts of the Vatican will have left the shores of the Tiber for those of the Potomac, the Hudson, the Mississippi, or the Sacramento.

Pharmaceutical Preparations.

OBSERVATIONS ON THE DIGESTIVE FERMENTS.

Dr. William Roberts, in the *British Medical Journal*, says: "If properly prepared, malt extracts are rich in diastase, and have a high power in digesting starchy matters. But you will be surprised to learn, as I was, that a large proportion of the malt extracts of commerce have no action on starch. This is owing to a high temperature having been used in their preparation. Any heat above 150° Fahr. is destructive to diastase in solution ; so that if the extract be evaporated, as is directed by the German Pharmacopœia, at a temperature of 212° Fahr., it is necessarily inert on starch. Out of fourteen trade samples of malt extract examined by Messrs. Dunston & Dimmock, *only three* possessed the power of acting on starch. These brands were Maltine, Corbyn, Stacy & Co.'s Extract, and Keppler's Malt Extract."

Items.

—The estate of a rich man is hallowed ground to the lawyers, and they will travel for hundreds of miles to prey upon it.

—Terra alba, or white earth, is used to adulterate white sugars, cream of tartar, and other commonly used articles. Its use tends to produce disease of the kidneys, bladder and stomach.

—Some men are inconsistent creatures. They will get up in the middle of the night and throw their boots at a dog because he is howling at the moon, and the next night pay five dollars a seat to hear Italian opera.

—The tower of the beautiful old church at Hempstead, in Essex, in which repose the remains of the immortal Harvey, has crumbled and fallen to the ground. Dr. Benjamin Ward Richardson is soliciting subscriptions to rebuild it.

—A Milwaukee naturalist stated in his lecture that a black bear could hug seven times as hard as a man, and the next time a menagerie visited the town every girl in the crowd made eyes and waved her handkerchief at the black bear, and paid him so much attention that he got confused and blushed.

—The new officers of the Philadelphia County Medical Society are: President, H. Y. Evans ; vice presidents, Charles K. Mills, John B. Roberts ; treasurer, William M. Welch ; recording secretary, Henry Leffman: reporting secretary, Frank Woodbury ; corresponding secretary, H. Augustus Wilson ; assistant secretary, J. D. Nash, and librarian, M. O'Hara.

OBITUARY NOTICES.

JOSEPH PANCOAST, M.D.,

On March 7th, 1882, Joseph Pancoast, M.D., Emeritus Professor of Anatomy in Jefferson Medical College, died, at his residence, No. 1030 Chesnut street, of pneumonia, having reached his seventy-seventh year. His illness was of very short duration. He became prostrated, and his suffering from congestion of the lungs was acute. His condition steadily grew worse, death finally coming to his relief. He was attended by his son, Dr. William H. Pancoast, and Dr. Da Costa.

Dr. Pancoast was born in the year 1805, in Burlington county, New Jersey. Adopting the profession of medicine and surgery, he studied the same at the University of Pennsylvania, and graduated in 1828, with the degree of M.D. He at once commenced practice and made surgery his specialty. He began teaching practical anatomy and surgery in 1831, and during the same year edited a "Treatise on the Structure, Functions, and Diseases of the Human Sympathetic Nerve," by J. Frederick Lobstein. In 1834, he was elected one of the physicians of the Philadelphia Hospital; shortly afterwards, physician-in-chief of the children's hospital in the same institution; and from 1838 to 1845 he was one of the visiting surgeons to the same hospital. In 1838 he was elected Professor of Surgery in the Jefferson Medical College, succeeding Dr. George McClellan. In 1844 he published his "Treatise on Operative Surgery," which he revised and enlarged in 1852, when it had passed to a third edition. During the first nine years of its existence 4000 were sold. He also, in 1844, remodeled the able work (originally written by Dr. Caspar Wistar, to which the late Professor William E. Horner had made valuable additions), entitled "A System of Anatomy for the Use of Students." On March 27th, 1854, he was elected one of the surgeons of the Pennsylvania Hospital, and resigned that position on February 29th, 1864; in 1861, Professor of Anatomy in Jefferson Medical College, from which he resigned in June, 1873, his son, Dr. William H. Pancoast, succeeding him. Directly after his resignation, Dr. Pancoast was elected Emeritus Professor of Anatomy.

He filled for a period of thirty six years, successively, two of the most important chairs in that celebrated school. He also edited, at sundry times, "Manee on the Great Sympathetic Nerve," and the "Cerebro-Spinal System in Man," by the same author, and subsequently "Quain's Anatomical Plates." He was a voluminous contributor to the *American Journal of the Medical Sciences*, the *American Medical Intelligencer*, and the *Medical Examiner*, besides publishing various monographs, both pathological and surgical, and, at the time, the novel department of plastic surgery. He also published sundry essays and introductory letters to his class; the one of 1865 is entitled "Professional Glimpses Abroad." He was a member of the American Philosophical Society, of the College of Pharmacy and other scientific institutions. He was an eminent surgeon, bold, rapid, and skillful with the use of the knife, and in diagnosis almost invariably correct.

Among the many new operations devised by him was one for soft and mixed cataracts upon the eye; in 1841, a new process for removing cystic tumors; a quick process for correcting strabismus. He afterwards demonstrated that after the eyebrow had been destroyed a good-looking substitute could be made by raising a flap of the scalp, with the soft, drooping hairs of the temple, and giving it a long pedicle, to run in a bed cut for it up to the brow. He four times performed, with success, a lumbar operation for large abscesses lying in the connective tissue between the colon and cæcum and the front of the quadratus muscle. Later, he found that by cutting the posterior muscles of the velum palati at a certain point, a voice that was unintelligible could often be restored. He was the originator of the operation for the relief of atrophy of the bladder; performing it first in 1868, and it has since been followed here and in Europe. Amputations at the hip joint or even high up on the thigh, were formerly very fatal operations, from the excessive loss of blood. Far more patients died than recovered from these operations Dr. Pancoast devised a plan to prevent this by using the abdominal tourniquet, with a large roller compress over the lower end of the aorta, so as to shut off all the arterial blood from the lower limbs.

He found by trial that the patients could respire freely with this pressure, under ether, so as to give all necessary time for the operation. In June, 1860, he performed this operation on a large, muscular man at the Pennsylvania Hospital, and the patient lost but three ounces of blood, and rapidly recovered. His plan is now followed in all such cases in this country. In fact, it is now almost the fixed process.

There are cases of tic douleureux, involving all the branches of the second and third divisions of the fifth pair of nerves, producing for months and years horrible suffering, and for which there is no relief but the division of the trunks of these nerves, as they come out of their foramina, at the base of the skull. He devised a plan which he has successfully practiced and which has never failed of giving relief to the sufferer. Few men have contributed so many processes to the surgical profession as the great anatomist who has just passed away.

QUERIES AND REPLIES.

Dr. J. L. B. asks our correspondents "What proportion of men among their patients are affected with stricture of the urethra."

Dr. J. W. McC. You will find your query answered in "Special Report" No. III, in our issue of March 4th.

H. N. You can vaccinate a person who has eczema, without fear of any bad results.

MARRIAGES.

BURTON—STURTEVANT.—At Dover, Massachusetts, October 26th, 1881, by Rev. C. C. Sewall, Dr. C. W. Burton, of Adams, Massachusetts, and Miss Isabel Sturtevant, of Dover.

EMERICK—VORIS.—February 23d, 1882, at the residence of the bride's father, Gilbert Voris, Esq., near Potts' Grove, Pennsylvania, by the Rev. H. G. Finney; H. M. Emerick, M.D., and Annie M. Voris.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

MENTAL ASPECTS OF INFANTILE UNFOLDMENT.

BY THOS. S. SOZINSKEY, M.D., PH.D.,
Of Philadelphia.

In an article which appeared recently in the Reporter, I treated of various physical aspects of infantile unfoldment, the basis of my remarks being observations made on a male child (my own) who was healthy at birth, and was cared for properly from day to day. Taking observations made on the same child as the basis of my remarks, I will now treat briefly of some mental aspects of infantile unfoldment. This subject may or may not be of much value practically to physicians as such, but nevertheless it is eminently worthy of their attention, as well as that of thoughtful people in general. The discussion of it in a medical journal may not be entirely in place; but this should detract nothing from its interest. The two articles being supplemental to each other is, perhaps, sufficient reason for their appearance in the same periodical.

The mental unfoldment of children is a subject which, indeed, has received comparatively little attention as yet, but more, perhaps, than one might suppose from reading the extract from the circular to be given below. The celebrated Mr. Darwin has written a sketch of one of his children, M. Taine, the distinguished French litterateur, one of one of his, and Mr. Pollock, an English scientific essayist, one of one of his. The two authors last named dwell almost exclusively on the unfoldment of the power of speech. Among other writings on the subject with which I am acquainted are some by Preyer and by Perez, the former a German and the latter a French scientific author. All these are recent productions, and altogether are very far from being exhaustive.

Now, it may be well to explicitly say that the mental unfoldment of a child is very largely dependent on the impress of external influences; it does not occur, as many erroneously suppose, spontaneously. However healthy a child's brain may be, it will never have a well developed mind, if impressions of the right kind are not made on it, and made on it, too, in the right way. This truth does not seem to be known to some who are presumably versed to some extent in scientific knowledge; even the Educational Department of the American Social Science Association seems to be oblivious to it, if one may judge from a circular sent out by it to parents, last year, for the purpose of obtaining data to indicate the rate of development of the powers of the mind. In this circular replies to a large number of questions were asked for, but none as to the shaping external influences at play. The purpose of it, however, was good. It contained the following introductory remarks:—

"We have been made familiar with the habits of plants and animals, from the careful investigations which have from time to time been published—the intelligence of animals even coming in for a due share. One author (Lord Lindsay), alone contributes a book of one thousand pages upon 'Mind in the Lower Animals.' Recently some educators in this country have been quietly thinking that to study the natural development of a single child is worth more than a Noah's Ark full of animals. Little has been done in

this study; at least, little has been recorded. It is certain that a great many mothers might contribute observations of their own child's life and development, that might be at some future time invaluable to the psychologist."

"The natural development" of a child is something, I ween, which the Association will not soon become familiar with. Human beings are not, and cannot be expected to be, all similar in their mental development, as are some species of dumb animals. No; the development of the mental faculties of a child is in all respects greatly dependent on the character of its environment. A child whose mother or nurse takes little interest in it need not be expected to progress well, either physically or mentally. That from what the child is, a fair idea of what the parents, but more particularly the mother, are may be formed, is a true old saying.

Of course, it will not be inferred from the remarks just made that I believe that a child's mind at birth is, as it were, a mere blank page on which characters may be written at will. A child at birth has ingrained in its constitution the character of its ancestors for generations back. It may be possessed of special susceptibilities of an admirable or of an unadmirable sort. Still, as has been said, the environment of a child is extremely potential for good or bad.

The question is often asked, does a child at birth know anything? The answer is, No; it knows nothing. All that any one can ever know is gained through the exercise of one or other of the five senses; and not one of these is then in any other than a budding condition. A newborn child can hardly see; it can hardly hear; it can hardly smell; it can hardly taste; it can hardly feel. It takes time to unfold the power of every one of the senses; indeed, their unfoldment may continue at least until the decline of life begins. And simultaneously with the unfoldment of the power of the special senses unfolds the powers of the mind. The first impression that arouses consciousness, however faintly, whether it be received through one or other of the five senses, is the first step in the acquirement of knowledge. But there is only a glimmering perception of anything at the start, and the ability to recognize likeness or difference in things is of gradual and slow growth. The reflective power of a child under a year of age is very, very feeble. Had Dr. Holland studied infantile life carefully, he would likely not have written the misleading passage in "Bitter Sweet," beginning—

"Who can tell what a baby thinks?"

In what has just been said, the idea is implied, and properly, I believe, that at first a child is not easily hurt; acuteness of feeling is developed by degrees. The crying of a young infant is not necessarily caused by pain; when it is caused by pain the influence at play to produce the latter must be decided. This obtuseness of sensibility in tender babyhood is a provision of Nature, which is fortunate in the case of many a little creature.

It can hardly be doubted that even a newborn child is possessed of some degree of sensibility to pain. Whether or not it is possessed of some degree of sensibility to pleasure is a more open question, I believe. Assuredly, it is possessed of a decided degree of sensibility to both within the first month. And here I may observe that it should be known by every one, that just as soon as a child can experience pleasurable and unpleasurable sensations, just so soon is it possible and proper for systematic training to begin. Most of the talk which is indulged in about the impropriety of beginning education early is sheer nonsense; it cannot be begun too early, or be too energetically carried on, if it be of the right kind, and be rightly conducted. On this, as on many another subject, one can refer with advantage to the teachings of the sages of antiquity. "Pleasure and Pain," says Plato, "are the first perceptions of children," and continues, "The particular training in respect of pleasure and pain, which leads one always to hate what one ought to hate, and love what one ought to love, from the beginning to the end, may be separated off, and in my view, will be called education." Yes, that is really at least the supremely significant part of education; it is the part which has an active bearing on the conduct. In his work on the emotions and the will, the English philosopher, Bain, gives expression to melancholy truth when he says, "It is not usual to commence the discipline of children in the first year of life." Such parental dereliction is inexcusable. From the very start, what is right should be encouraged, and what is wrong should be discouraged. Let right feelings and emotions and manifestations of will be fostered and wrong ones repressed, from their inception forward. Parents who put off disciplining their children until their understanding is well developed, are deliberately letting bad traits get such firm rooting in their nature that their removal cannot be accomplished without much difficulty. Plutarch, in his essay on the "Management of Children," rightly declares it to be "Expedient that manners be well-

fashioned from the very beginning. For childhood is a tender thing, and easily wrought into any shape. . . . As soft wax, is apt to take the stamp of the seal, so are the minds of children to receive the instructions imprinted on them at that age."

On the day on which the child was four weeks old, it is recorded of him that "he clearly notices objects, particularly if bright, and follows them readily with his eyes when moved." Doubtless long before this impressions were made on the eye, attended with more or less consciousness. Even at a week after birth it is possible to make almost any infant follow an object with its eyes. Thus early does a child begin to learn; and it begins to learn not only through the eye, but through each of the other special senses. In respect to the sense of sight, I may further say, that for several weeks at first, in infants, there is reason to believe that the field of vision is composed merely of light and dark areas; and that degree of brightness only is appreciated. The sense of color is wanting; an infant is for some time completely color-blind. According to Preyer, blue is the last color to be correctly perceived. How soon a child shall be able to recognize any or all colors and their shades, is for the most part a question of opportunity to learn, and the effort its care takers may make to teach it.

I may here observe that tears do not flow freely until between the sixth and ninth week of age—a circumstance due largely to the fact that decided emotions are not experienced earlier. Subsequently, when a child cries and there is a flow of them, it is an indication, as a rule, of injured feelings. Crying unattended with tears is indulged in voluntarily, for a purpose.

From statements made above, it, of course, follows that the popular idea that a child does not "begin to notice" until it is five or six weeks old, is an error. The error arises probably from confounding mere noticing with obvious discrimination or recognition of similarity or difference in things. But it cannot be doubted but that most children have some power of discrimination before their fifth or sixth week. On the day the child was three weeks old it is recorded of him that "he evidently recognized his mother's breast, when brought into view, and was evidently pleased to see it."

When the child was six weeks old it was stated of him in the record that "for several days he has certainly been able to distinguish his mother from others." This means that at the age indicated the ability to at least identify an object was manifestly present; which ability implies the retention in the memory of an idea or mental image; for without the possession of memory the identification of an object seen before would be impossible.

When a child can identify its mother it must certainly be possessed of the ability to recognize differences too; for if there is no ability to recognize differences, of course, it would be impossible to distinguish an object seen before from others. Hence there is sufficient reason to believe that as early in life as the sixth week after birth the basal intellectual faculties, namely, the power to recognize likeness, the power to recognize difference and memory, are present, but, to be sure, only in their incipiency, even in the brightest of children.

It is recorded of the child that at seven weeks of age he would smile on being tickled. Far earlier than this smiles were observable, but likely they were not expressive of pleasurable feelings. Mr. Darwin's child manifested a sense of pleasure by smiling on the forty-fifth day. It is probable, however, as stated already, that considerably before the seventh week both pleasurable and unpleasurable feelings are experienced to a degree. By the time the child was three and a half months old he indulged frequently in loud laughter. It has been said that taste is the first of the senses to yield pleasure and smell the last.

When the child was three months old he apparently made some effort to imitate sounds, especially that produced by pronouncing the syllable "goo." It is probable that any imitation of sounds which he then made had little if any intellectual basis. In the record of his child, Mr. Darwin remarks, "When our infant was four months old, I thought that he tried to imitate sounds, but I may have deceived myself, for I was not thoroughly convinced that he did so until he was ten months old."

When midway between his third and fourth months, the child appeared to know his name (Thomas); at any rate, when it was pronounced he would turn his eyes in the direction from which the sound came. Of the Darwin baby it is recorded that "he was not able even when a hundred and twenty-four days old easily to recognize whence a sound proceeded, so as to direct his eyes to its source."

The first evident indication of preference of persons was shown by the child a few days before he was four months old. On being placed in the arms of a stranger he made decided efforts to get away.

At three and a half months the child took

notice of his hands. It is probable that when this is done there is some sense of individuality, a dawning recognition of self as something distinct from other things. It is questionable, however, I believe, whether any child has a well-defined sense of individuality or self-consciousness until long after it is a year old, and in many cases a considerable time after use is made of the words "I" and "me." It is said by Preyer that in the fifth quarter a child may bite its own hand so badly as to produce crying; but I think it would be a very stupid child of over a year old who would do that. Tennyson speaks of this matter so interestingly that it is worth while to quote the following stanzas:—

"The baby, new to earth and sky,
What time his tender palm is prest
Against the circle of the breast,
Has never thought that 'this is I.'

"But as he grows he gathers much,
And learns the use of 'I' and 'me,'
And finds 'I am not what I see,
And other than the things I touch.'

"So rounds he to a separate mind,
From whence clear memory may begin,
As thro' the frame that binds him in,
His isolation grows defined."

On reaching the end of his seventh month the child could, in addition to being able to make various vowel and a few other sounds, say, "dada," "papa," and "baba." Before this period the sounds made were not of an articulate character. Six weeks later he could say "mama"—syllables which are erroneously supposed by most people to be about the first to be made use of by children—"dādā" and "dā." When ten months old he could pronounce with considerable distinctness the words "car," "girl," and a few others, and had undoubtedly some knowledge of their meaning. A week or two subsequently the phrases "take care," "bye bye" (good bye), and several others, were in frequent use by him. When a year old his vocabulary consisted of about a score of words. His power of speech was not remarkably well developed at the end of the year, but it was decidedly better than in many children, among them being Mr. Pollock's girl.

It is hardly necessary to say that there is no ground for the idea that a child tends naturally to speak what is ignorantly supposed to be the original language of the human race, namely, the Hebrew, an idea which I have often heard expressed. An infant at first has "no language but a cry," to use the words of Tennyson, and apart from, perhaps, some special adaptation of the organs of hearing and speech for the mastery of the language of its ancestors, due to inheritance, it tends to learn all languages with almost equal facility. The knowledge of the names of things, and the ability to express ideas properly, are acquired gradually; and indeed such acquirements, in the nature of things, may go on improving for life. For a long time a child has more ideas than it has language to express, as every one familiar with children well knows.

At eight months and ten days old the child manifested clearly a sense of fear. On bringing a dog into his presence he had a strong desire to place his hand on it, but hesitated long before he actually touched it, and when he did touch it he recoiled from the animal quickly. But let it not be supposed that thus early, or even when a year old, he was alive, to any great extent, to more than a few special dangers. It may be reasonably presumed, however, that some feeling of fear may be experienced as soon as one sensation can be readily distinguished from another, as those produced by the sight of different objects. Any strange impression, if decided and made abruptly will excite fear.

In this connection, I may observe that the emotions of a child may be intense, but are, as a rule, short-lived. By diverting the attention, apparently great distress can generally be made to vanish almost instantly. This susceptibility to impressions, and changeableness of feeling of children should never be lost sight of by their attendants.

An entry in the record made when the child was nine months old runs thus: "It is easy to get him to relinquish anything he has by presenting something else that is novel;" and this is followed by the following inference: "Evidently his memory is yet extremely short." Obviously this is another peculiarity of young children which can be taken advantage of to good purpose in their management.

It was when between nine and ten months old that the child began to have an appreciable ability to take an interest in more than one thing at the same time. This ability gathered force slowly. When even a year old, he did not hold an object in either hand at once with great ease; he was greatly inclined to drop one or the other. In truth, the power to take an interest in two things at once is not very decided in many that are several years old.

It was not until the child was nine months old that he gave any clear indications that he understood anything that was said to him. When asked then, "Where is the little boy?"—meaning a little picture which he had long been in the habit of looking at—he would look and point at

it. Three months before that, when a person held out the hand and said, "Shake hands," he would extend his; but it is, perhaps, certain that he did not do this as an intelligent compliance with a request. But for some time expressions of approval or disapproval were understood in a measure. At nine months it is said of him in the record, "The tones in which he is spoken to are evidently well understood and have been for some time;" and again "It is easy to teach him what he may or may not do. He will not take hold of forbidden things."

As has been implied in preceding remarks, when the child was at the end of his first year he was but to a very limited extent subject to the guidance of intelligence; he understood but little of what might be said to him, and that little was understood very imperfectly. This is equivalent to saying that children under a year old must be guided almost wholly otherwise than through the intellect. Anything which such children may do from time to time, of their own accord, that is proper, is done mainly through habit; it is done for the most part automatically. Hence, it is extremely important to inculcate good habits. Happily, this is easily done, as already intimated; and it may be begun almost at birth. Let the infant be led to behave for a time or two as desired, and it will afterwards do so of itself. Especially in reference to sleeping and feeding at set periods, can force of habit be brought into play to great advantage.

From remarks made it is evident that at the end of his first year the child's mental activity was decided. His different senses were then alive to impressions, and his emotions and intellectual and volitional powers were all of more or less force. Very much did he at that period, and considerably before, enjoy exercising his powers. And when it is done agreeably and gently, and not carried to the point of excess, it is advantageous for a child to exercise all its good powers, for in this way do they become stronger and more subtile. Such exercise should, of course, be encouraged, and the proper direction of it is or should be regarded as the main part of the art of education, household and otherwise.

I will now conclude. I have made a considerable number of remarks; but many more might be made without exhausting my theme. I would express the hope that what I have said in this essay, and the one referred to above, will lead many another to indulge in similar study. Such study well repays the observer by the pleasure it affords; and the welfare of the infants of the race is clearly bound up with it, which, of course, means, eventually, the welfare of the whole race. Well, indeed, is it, then, for every little innocent's parents to take an active interest in it, or, as the poet (Montgomery) says—

> "To mark its growth from day to day,
> Its opening charms admire,
> Catch from its eye the earliest ray
> Of intellectual fire;
> To smile and listen while it talks,
> And lend a finger when it walks."

IDIOPATHIC RETRO-PHARYNGEAL ABSCESS.*

BY ALEXANDER W. M'COY, M.D.,
Of Philadelphia.

In making some remarks upon the subject of retro-pharyngeal abscess, the writer is aware that the subject has received masterly treatment at the hands of some of the most distinguished surgeons of the past, as well as from those of our own time.

It is not with the intention of adding anything new concerning this affection that this paper is written. All the writer wishes to offer is the report of a case, of idiopathic origin, which came under his care a few months since; and also call attention to this rare and interesting pathological condition.

In the early part of August, 1881, John Carlin, aged 24, native, single, and a printer by trade, first presented himself for treatment at the Throat Department of the Jefferson Medical College. His statement was to the effect that he had always enjoyed good health, had not contracted syphilis, and had a good family history.

In November, 1880, after having played upon a trombone, the exercise was followed by a considerable hemorrhage from his lungs, which continued to recur in less amount for several days. but which yielded readily to treatment, and he suffered no injury to his health; nor did he lose any time from his occupation. In July, (one month previous to his presenting himself as a patient at the Throat Department of the Hospital) he was on a fishing excursion down the Delaware. His boat came in contact with a schooner; to save himself he jumped into the river and swam ashore.

One week after this accident he first noticed stiffness in his neck, which made rotation or flexion of his head painful. A few days afterward he began to find deglutition difficult and his "food stuck in his throat" (as he expressed it) and was regurgitated soon after. When he attempted to swallow fluids they came out of his

* Presented and accepted as a Candidate's Thesis, by the Philadelphia Laryngological Society, at meeting held January 27th, 1882, and published by order of the Society.

nose. He suffered much from severe pain in his throat, which at times was of a lancinating character, shooting up into and behind the ear. This sharp pain was greatly increased on movement of the head. All these symptoms continued, gradually increasing in severity up to the first visit to the hospital—one month from the date of his first symptoms.

On examination with a good light, the wall of the pharynx, on the right side, was seen to be of a dusky mottled-red color. There was great bulging of the back of the pharynx on the right side. This bulging extended half an inch above the soft palate. The swelling increased in prominence from above downward, until on a level with the top of the larynx, where it appeared greatest. The swelling filled up the space on the right side of the pharynx, and extended well over the median line. The redness was coextensive with the bulging, and was sharply defined where it ended. There was not the slightest swelling or œdema of the adjacent tissues.

On examination with the finger, the swelling was found to be elastic. Fluctuation could be readily felt on moderate pressure along the whole swelling.

This bulging gradually increased downward, encroaching upon the space of the gullet, until, when opposite the superior margin, and to the right of the larynx, the tension was so great that the finger could not be pressed further. The swelling appeared to be confined to the right side, for the most part, and no swelling or œdema of the epiglottis or larynx could be felt.

Laryngoscopy revealed the same conditions, but owing to the encroachment of the swelling a view of the inside of the larynx could not be obtained. His voice was unimpaired.

The treatment consisted of a small longitudinal incision with the bistoury in the upper third of the swelling. This gave rise to a free flow of white, creamy, inodorous pus. The dependent part of the abscess was emptied by pumping it out with the end of the finger, slowly pressed on it from below upward, until the contents were evacuated. This manœuvre was repeated three times a week, as the pus accumulated from time to time, until, at the end of twenty-four days the sac of the abscess had become completely closed. The tissues remained thickened. A firm ridge could be felt over the entire tract of the former abscess. This gradually disappeared. On examination one month afterward the tissues appeared normal.

Remarks.—This case appears to coincide with the experience of Bokai (whose very valuable and unique paper upon this subject is quoted so frequently by writers) in *this*, that it occurred *idiopathically*. Bokai's report is exceptional in showing such a large percentage of idiopathic cases, so many recoveries, as well as such a large personal experience.

Of 144 cases seen by him, all but 13 were idiopathic. In this record he differs totally from all other observers, who believe that the greater number of these cases are caused by disease of the vertebræ, and who make syphilis the prominent factor in its causation.

Hospital Reports.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

CLINIC OF FRANCIS DELAFIELD, M.D.,

Adjunct Professor of Pathology and Practical Medicine.

Perinephritis and Cirrhosis of the Liver.

Gentlemen:—This patient is a boy, sixteen years old, who was admitted into the hospital September 20th. He is a printer by trade, and has been in the habit of standing in front of a printing press and leaning over to feed it. For some time past he has had slight pains in the abdomen and side, and he has ascribed these pains to the position in which he worked; but still he was pretty well until a week before his admission into the hospital. At that time he began to have very severe pains in the right iliac fossa, and he at once felt very sick, very much prostrated. He had repeated rigors, followed by febrile movement, and he had headache. To repeat, a week before his admission he was taken suddenly sick with rigors, with a febrile movement, with marked prostration, and with very severe pain referred to the right iliac fossa. The pain and the febrile movement continued, and there was some cerebral disturbance. He was delirious, especially at night. His bowels did not move at this time. He continued in this condition until he was brought into the hospital, with the exception that the constipation which had previously existed was succeeded by temporary diarrhœa. When the patient was brought into the hospital it was evident that he was suffering from a serious illness of some kind. He complained of the pain in the abdomen, which he referred to the right iliac fossa, very bitterly, and there was also very marked tenderness, and the patient lay in bed with his thighs drawn up, apparently to relieve the pain. No tumor could be felt in the abdomen. There was some tympanites. His temperature at this time was 102° F., his pulse 100. The patient was put partly under the influence of opium, and was in this way made more comfortable; but his temperature continued high, ranging between 102° and 104.2° F. The bowels were sometimes loose, sometimes constipated. The pain in the right iliac region still continued, although no tumor could be felt there. Matters continued in this condition until the 25th of September, when it was noticed that

the right lumbar region behind was becoming fuller than the left; that the skin and subcutaneous tissue felt œdematous, and it seemed that there was an abscess deep down in the tissues of the back. The temperature during this time continued pretty high, and the prostration was still marked. On the 26th of September an incision was made over this swelling in the right lumbar region behind, and when some depth had been reached a large amount of fetid pus was discharged. The opening was made pretty free and a drainage tube was inserted, so as to allow the pus to escape. The gentleman who made the incision introduced his finger and found that the cavity of the abscess was large, and he thought the kidney was pushed forward. The patient was made more comfortable by this operation; the temperature fell and his general condition improved. Since then he has been going on in very much the same way; when the discharge from the abscess is free his temperature falls to normal, and his general condition is good; but from time to time the drainage of the abscess appears to be no longer complete; there appears to be an accumulation of pus, and then the patient's condition is not so good; his temperature runs up, and he does not do so well. This abscess, therefore, has not yet healed up; it still discharges pus, and shows from time to time an inclination for pus to accumulate in it, and then the temperature runs up and the patient's condition is worse.

As we look at the boy at the present time, his appearance is not bad. He is rather pale, but his lips are of a fair color; he is somewhat emaciated, but not very much so. The drainage tube is still in the place where it was first inserted, in the right lumbar region, a little above the crest of the ilium, and the internal end of the tube points upward, showing that the pus cavity is up in this direction. The abscess, therefore, lies up about under the twelfth rib on the right side, pretty close to the spinal column.

Now, what is the diagnosis? "Perinephritis." That is highly probable. Does anything else suggest itself. "Perityphlitis." That is possible. "Psoas abscess." That is not likely. "Perforation of the colon." The history does not point in that direction. "Caries of the spine." That is not likely, with the previous history of the patient.

Perinephritis and perityphlitis are the two conditions that the diagnosis lies between. It is pretty certain that it is one or the other. To be more exact, we want to know exactly what is meant by the terms perinephritis and perityphlitis. By perinephritis we mean suppurative inflammation of the connective tissue about the kidney, usually behind it; and by perityphlitis we mean suppurative inflammation of the connective tissue about the vermiform appendix. In neither case need the kidney or the vermiform appendix themselves be involved in the inflammation. These parts may be involved, but it is perfectly possible to have inflammation of the connective tissue about the appendix or kidney without their being involved at all. In this particular patient there is no reason for supposing that there is any disease of the kidney, or of the appendix, but there is reason to believe there is suppurative inflammation of connective tissue. Well, when we get as far as this we have really gotten about as far as we can go. If you make up your mind that you have a case of suppurative inflammation of connective tissue situated just behind the peritoneum, it really is a matter of very little consequence whether this connective tissue is behind the kidney or whether it is behind the vermiform appendix, and in either case the situation of the inflammation would be very nearly the same, for there is only about an inch distance between these two portions of connective tissue. If we start with the supposition, which is probably the correct one, that neither the kidney nor the vermiform appendix has anything to do with the matter, you observe that we come to the fact of a local suppurative inflammation of connective tissue without known cause. We do not know why a person gets up a suppurative inflammation of this particular part of the body, and whether it occurs about the appendix or about the kidney is a matter of very little consequence. The process is essentially the same in the two conditions. Generally speaking, however, if the inflammatory process involves the connective tissue around the appendix the tendency of the collection of pus is forward, and when the abscess is opened it is usually opened in front, not behind. On the other hand, when the connective tissue about the kidney becomes involved, the tendency of the pus is to burrow backward into the muscles of the back, and when the abscess is opened it is opened through the skin on the back. For this reason I should infer that in this case the inflammation has existed in the connective tissue about the kidney, and not about the vermiform appendix, although I cannot at all deny the possibility of the latter being the case.

No pus has escaped with the patient's stools, and we may conclude that the colon has not been involved. Whether the pus be situated in the connective tissue about the kidney or about the appendix, it is always possible for it to perforate the caput coli, and for the abscess to empty itself into the large intestine in this way, and its contents be discharged with the stools.

Now, what are we to apprehend in this case? This abscess has been open and discharging pus since the 25th of September, but sometimes not freely, and at those times the patient has febrile movement. "We have to fear pyæmia, perforation of the peritoneum, resulting peritonitis." Those are two real and serious dangers to be apprehended, pyæmia and peritonitis, from perforation or extension of the inflammation. Is there any other danger? "Empyema." Yes, that is possible. "Amyloid degeneration." Yes, if the case should go on in this way, not developing peritonitis, septicæmia, nor empyema, and yet the suppuration continuing, there would be serious danger of there developing amyloid or waxy degeneration of the different viscera.

Now, what can we do to lessen the probability of these dangers? Here we come, perhaps, rather to a surgical than to a medical question, and yet it is a question which might arise in the medical practice of any one of you. "Enlarge the opening." The opening has been enlarged several times and yet the emptying of the abscess

is not satisfactory; and the cavity was washed out through a drainage tube, with antiseptic fluid, and yet that does not prove satisfactory. "Give the patient constitutional treatment." Well, after all, the trouble is local, not constitutional, and if the local trouble cannot be improved there is no constitutional treatment that will make any difference in the case. Of course, however, the boy should be kept in as good condition as possible. "Injections of iodine." I do not know that injections of iodine would be likely to do any more good than injections of carbolic acid. You would be afraid to inject strong iodine, and weak iodine would simply act as does carbolic acid, as an antiseptic.

Well, it seems to me that what is needed is a counter opening.

I think the trouble is, and it is a trouble which cannot be gotten rid of as things are at present, that the abscess has never been fairly emptied. You would say, very naturally, that the position is not at all a favorable one for a counter opening, and yet I think it would be quite possible to make one. In order to do that you would remove the drainage tube and introduce a blunt-pointed probe into the opening, upward and sideways, not backward, and try to bring the blunt point pretty near to the skin without risk to the peritoneal cavity, then cut down upon the point of the probe and introduce a drainage tube from one end of the wound to the other. Then it would be possible to wash out the cavity. Of course, I do not know, not having tried it, that this could be done, but without a counter opening it will continue almost impossible to wash out the cavity of the abscess thoroughly, and remove all the pus from every little pouch, and until this can be done there is little hope for improvement in the patient's condition.

Cirrhosis of the Liver.

You may remember that last week I showed you a young man who was very dropsical; there was very great distention of the abdomen, there was some œdema of the legs, and the history was that of cirrhosis of the liver, which had developed pretty rapidly, which had been accompanied by marked dropsy and by marked depreciation of the general health, and there were at the same time some changes in the urine, and I told you that the patient was a good example of that form of cirrhosis in which there is developed both dropsy and change in the nutrition of the patient. Both of these symptoms were very marked, and though we could not make out the size of the liver by either palpation or percussion, the dropsical effusion being so great, we remarked that it was probably quite small.

The patient died a few days later, and here is his liver, presenting a characteristic hob-nail appearance, and quite small. The spleen is very much enlarged, as you would expect in cirrhosis. The kidneys, which we supposed at the time would turn out to be atrophic kidneys, are not atrophied; they are nearly of normal size; but, although this is the case, they still belong to the atrophic variety of chronic diffuse nephritis. It is the atrophied kidney still in the earlier stages, before the kidney has become diminished in size.

I now present to you another patient, a man fifty years of age, who has been in the hospital a long time—since 1879. The first trouble which he had was swelling of the abdomen, and he had with this some dyspnœa, a little disturbance of the general health, and a little jaundice. He also was troubled with the piles. Since that time up to the present, he has been in the hospital on and off, and has been tapped repeatedly. After being tapped he is relieved for a time, then the abdomen again becomes distended with fluid, when he is re-tapped, and this has been going on now for several years, and yet you will observe that at the present time the patient's condition is good. You will observe that he now has considerable ascites, that his general appearance is good, his lips are of a fair color, and he is not particularly emaciated; his liver is diminished in size, his spleen is somewhat enlarged. There is no œdema of the legs.

This, then, is another case of cirrhosis of the liver which has caused ascites, and has lasted for a considerable length of time. But why his general condition should be good, while that of the former patient was so bad, is a question. If we could see this man's liver and spleen, we should probably find them in very much the same condition that we found those organs in the other patient, and yet in that patient the general condition was very different from what it is in this. Now, what is the reason of this? "There is very little functional disturbance of the liver in the last case." Yes, the liver, although it has undergone marked anatomical changes, is still able to perform its functions. This is a curious experience, although we are constantly meeting with it; we find the same fact to hold true with all the different viscera—with the brain, the heart, the lungs, the liver, the kidneys, the stomach, the intestines, that whenever these are the seat of an anatomical lesion there is greater or less disturbance of function, but the disturbance of function is not by any means always in proportion to the extent of the anatomical lesion. Why there should be this difference we do not know, but it is a thing which we are constantly meeting with, and it therefore becomes a matter of practical consideration. This man and the man whom you saw the other day, furnish two very good examples of it; both of them being patients suffering exactly the same anatomical lesion. I suppose that the anatomical lesion is just as far advanced in this man as it was in the other patient. In both patients there was the mechanical result of the anatomical lesion (dropsy), but in the former patient there was, in addition to this, a change in the general health, so great that the patient evidently died from want of nutrition; and in this second patient, in spite of the dropsy, the general health has continued good, so good that the man really would be well enough to go to work if it were not for the dropsy.

Then, in this last case you have a very good example of cirrhosis of the liver, of which dropsy alone is a symptom, while in the other patient you saw an example of cirrhosis of the liver in which both dropsy and disturbance of the general health were marked symptoms.

The patient whom I shall next show you is a man, fifty-four years of age, who was admitted

into the hospital on the 29th of November. The patient has been habitually intemperate, but still his health was good enough, or he considered it good enough, until the 19th of November, ten days before he was admitted into the hospital. Then he suddenly vomited up a large amount of blood, and for several days after this his fæces were of a black color, as if stained with blood. This vomiting and this discharge of blood with the fæces continued up to the time of his admission into the hospital. When he came into the hospital he was very feeble and very anæmic, and, as you see, he is rather white now, but he was very pale indeed, when he came into the hospital; both the skin of the face and the mucous membrane of the lips were exceeding pale, as if he had lost a large amount of blood. He was a little delirious. The temperature was 99.5° F. The specific gravity of the urine was 1.012, contained no albumen and no casts. He continued in this condition, very feeble, very anæmic and delirious, passing blood from the bowels, but no longer vomiting, until the 4th of December. Then the blood movements from the bowels ceased. The delirium, however, continued, although he was gaining strength and improving, and at the present time you will observe that he is able to sit up and walk about. His mental condition is better than it was; he is no longer delirious, but still his mental condition is not perfectly satisfactory. His color at the present time is pale, but he is not very much emaciated.

On physical examination, we find that the liver is a little increased in size, the heart is in its natural position, and only an anæmic murmur can be heard; the spleen is enlarged.

Now, what is the matter with the man? "Cirrhosis of the liver." On what do you base your diagnosis? "Disturbance of the function of the liver, enlargement of the spleen, hemorrhage from the stomach and intestines." He has an enlarged spleen, which would go with cirrhosis of the liver. He has had bleeding from the stomach, which is one of the symptoms of cirrhosis. The blood that was discharged by the stool I should suppose did not come from the intestine, but from the stomach; when passing into the intestine it was discharged through the rectum. Why should you suppose that there was functional disturbance of the liver? "He is somewhat emaciated and has some cerebral disturbance." He is not much emaciated, and the cerebral disturbance we might leave out of the question, there being other means to account for that, which we need not enlarge upon at present.

I think the only positive things we have, leaving out the cerebral condition, are the fact that he vomited a good deal of blood, so much that he became very much reduced, from anæmia; that this bleeding continued for about a week and then stopped, after which the patient began gradually to improve, and he has been improving up to the present time. More than this, there was no evidence of disturbance of the stomach; he had no pain about the stomach, he did not vomit except when he vomited blood, and he eats well enough at the present time. So that the case, after all, is one of bleeding from the stomach. The question, then, is, what is the cause of this bleeding. Cirrhosis of the liver is one cause which has been suggested as probably existing; is there any other? "There might be ulcer of the stomach." Yes, that, of course, may give rise to bleeding, and it may do so without there being present any other symptom; but still the rule is that when the patient's stomach is loaded he does have other symptoms in this condition; that he has vomiting and pain. Yet it is possible for a patient to have ulcer of the stomach and give no evidence of it but vomiting of blood, but the rule is otherwise. "Congestion, from an excess of alcohol." By that you would rather mean a chronic gastritis. That is a possible cause, but in that case the patient would be likely to bleed at different times and in moderate quantity; and then, too, we are apt to have other symptoms of chronic gastritis. "Malarial poisoning." Malarial poisoning, as a cause of bleeding from the stomach, I do not think we know much about in New York. "Cancer of the stomach." The patient is fifty-four years of age; an age at which cancer may occur, and this disease sometimes behaves in just the above manner; it will give no symptoms at all until the patient suddenly loses a considerable amount of blood from the stomach. Against that, however, is the absence of a cachexia, and the fact that the man has improved so much since the vomiting stopped.

The things which it would be possible for him to be suffering from are, cirrhosis of the liver, with obstruction to the venous circulation of the stomach; ulcer of the stomach; chronic gastritis; cancer of the stomach; and of these different conditions, the one which I consider most probable, taking the whole history of the case into consideration, is that of cirrhosis of the liver, with obstruction to a branch of the portal vein coming from the stomach.

So that you will observe this man furnishes us with still a third variety of cirrhosis of the liver; a variety in which there is no ascites, in which there is no interference with the function of the liver, in which there is simply interference with one part of the portal circulation, that coming from the stomach, and which has led to hemorrhage from the stomach and the man's present anæmic condition.

Medical Societies.

TRANSACTIONS OF THE OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, March 2d, 1882, Richard A. Cleeman, M.D., in the chair.

Mechanical Dilators in Gynæcological Practice.

Dr. Chas. H. Thomas had used the Ellinger dilator, and had been very much annoyed by a bad fault in the form of the blades. As soon as the instrument is opened the uterus shows a strong tendency to slip away from the dilator. This is due to the form of the outside edges of the blades, which gives to the dilator a wedge shape, with a difference of ten millimeters between the measurements of the base and apex. Conicity in uterine dilators is a dangerous quality; the instrument tending to slip in the direc-

tion of the base of the wedge. If the dilator when in use slips out of the grasp of the cervix it is likely to produce laceration ; while if it slip inward, as most dilators tend to do, it will wound the fundus uteri.

Dr. B. F. Baer said he had found the same objections, and had tried to overcome them by having an instrument so made that the mechanism by which the blades are separated is placed in the blades themselves, close to their points, and entirely concealed when they are in contact. This gives great power to a *small* instrument, and as the outer surfaces of the blades are perfectly parallel, and cannot feather, because of the position of the separating mechanism, the instrument does not slip out. I do not now need a tenaculum to hold the cervix in place, which is a great advantage. I have also had the handles bent down so that I can see just what the instrument is doing, and by a screw, so placed that it can be worked on the left with the left hand, while the right hand holds the handles and separates the blades, the dilatation can be done slowly and deliberately, with less tendency to slip out, and with less pain than with the old instrument.

With regard to the result of dilatation of the cervix for the cure of sterility, my experience is based upon the treatment, by dilatation with the steel instrument, of more than two hundred women who where sterile because of a defect in the calibre of the cervical canal, either from stenosis or flexion, resulting from imperfect development. Where the sterility was the result of obstruction, dysmenorrhœa was almost invariably present. This experience leads me to the conclusion that, although the canal is made so patulous by dilatation as to markedly improve the dysmenorrhœa, and in many cases to cure it permanently, the sterility remains, in the vast majority of cases, if the patient has been married more than three years before coming under treatment; and, if she had attained the age of twenty six, or twenty-seven years before marriage, then, though she come under treatment immediately afterwards, she will very likely be sterile. This will apply to the great majority of cases, but not to all. I think the reason may be stated as follows: The long continued hyperæmia of the uterus, the result of dysmenorrhœa, which probably existed from puberty, and especially from the non-fulfillment of the sexual function by conception, gives rise to such changes in the histological elements of the uterus that, instead of the organ being muscular, and therefore possessing its natural resiliency, elasticity and suction power, it is hard, fibrous, and non elastic. The mucous membrane lining the cavity also becomes so changed in its character that, if fecundation should take place, there is not a proper nidus furnished for the reception of the ovum, and it passes off without forming an attachment. The tissues of the fallopian tubes are likewise changed, and the tubes narrowed in consequence. This might explain the persistence of the sterility after the dysmenorrhœa has been relieved by dilatation of the cervix.

Dr. J. C. DaCosta had modified the Ellinger dilator by having the blades made very stiff and with a knob at the extremity, as in the uterine sound. When necessary he makes use of counter pressure over the fundus. In some cases he uses a small instrument first, to enable him to introduce the more powerful one through the internal os.

Respecting the statement of Dr. Baer, as to the incurability of sterility of three years' standing, he had recently had under treatment a lady who had one child seven years ago, but had since been sterile ; the uterus was sharply anteflexed ; a dilator was used for the relief of the flexion, and three months later the patient exhibited all the early signs of pregnancy.

Dr. Baer remarked that this case was not one of the class to which he had alluded. This patient had had a child, and anteflexion, probably the result of sub-involution and endometritis, was the cause of the sterility. Failure occurs in cases which have never been pregnant, and in which the uterus is enlarged, hard and changed in its histological character. He thinks it desirable to avoid multiplicity of instruments, and to have one dilator small enough to enter any os, and so arranged as not to yield to any pressure, but under all circumstances to preserve the parallelism of its blades.

Dr. Thomas thought that one reason why the sponge tent did good work, was because it worked slowly and continuously. Four years ago he made drawings of a modification of the steel dilator, to accomplish the same end. The instrument was made somewhat shorter than the ordinary one ; the blades were absolutely parallel on the outside edges and were approximated by means of a screw passing through a slot in one handle and attached to the other. A milled head traversed this screw, and between it and the handle of the dilator was placed a spiral spring or a soft-rubber pad. This instrument was intended to remain *in situ* for twenty-four hours, the spring making the action gradual and continuous, one or two turns of the screw being given every two hours by the doctor, or nurse properly instructed. The doctor thought that in this manner he could secure many of the advantages of the sponge tent, and at the same time avoid its dangers.

Dr. R. P. Harris had recently seen, in a foreign journal, diagrams of a very neat instrument to accomplish the same purpose. It consists of a C-shaped spring, to the ends of which are attached blades long enough to pass through the internal os. The fingers pressed upon the top and bottom of the C closed the instrument for insertion. Its action would be regulated by the strength of the spring. To obviate the danger of slipping too far into the uterus, a dilator with diverging blades could be furnished, with shoulders to rest against the cervix. The divergence of the points of the blades he considers an advantage ; the feathering reduces the apparent divergence in use, and that which remains helps to retain the instrument in place, particularly if the blades are furnished with shoulders. The dilating power is strongest where it is most needed, at the internal os. To meet an objection advanced by Dr. Thomas, he suggested that the shoulders might be made movable, to suit uteri of different depths. In every case in which a dilator is used the patient should be kept in bed until the direct effects are over.

He had recently under observation a case of dysmenorrhœa in which the dilator was used without effect, but in which a sponge tent effected a cure.

Dr. Baer thinks the blades should be parallel, and that dilatation should be uniform, without regard to the point of greatest constriction. Too much should not be expected from the dilator; a case of dysmenorrhœa could not be cured by one treatment; it is by the repeated use of the dilator, at proper intervals, that the best results are to be secured. As an instrument it replaces a set of graduated sounds, and the original inventor must have had that object in view. The contractility of the uterus must be overcome gradually; even when tents are used contraction will recur. The advantage of the dilator lies in its comparative freedom from danger, and in being less troublesome to the physician. It is indicated whenever there is constriction from any cause; for if there is not good drainage for uterine discharges, there will surely be irritation, resulting in endometritis.

The effect of the dilator on hypertrophy is the same as with sterility; if of long standing it is not curable; after the hard, fibrous stage is reached no reduction results from its use. But if the condition is recent, and the enlargement is of the muscular elements, or is due to engorgement, a cure may be secured; because here we have nearly the same condition which exists after labor, viz: a muscular uterus, having the power to contract and involute. I do not believe that chronic hypertrophy of long standing will, as a rule, yield to any treatment, but the symptoms to which it gives rise can be relieved, to a very great degree, in most cases.

Dr. Albert H. Smith regrets that Dr. Baer has not seen the admirable effects of the sponge tent on uterine hyperplasia. If you use a steel dilator in the uterus it can remain but a short time, practically not more than five minutes, giving a sudden mechanical dilatation, accompanied by probable rupture of the hardened fibres of the cervical canal; but it cannot give that stimulation to the contractility of the uterine muscles and to cell action that results from the use of the sponge tent, when no inflammatory action is existing. There is great resistance at first, but after the lapse of forty-eight hours the internal os and uterine walls have relaxed, spasmodic contraction ceases, and the vital power and muscular contractility of the uterus are developed by the presence of a foreign body which the natural powers will try to expel. Just as you have after the expulsion of an ovum a physical atrophy of the uterus, so you will have a similar action set up by the presence of a sponge tent in the cavity of the uterus. No such result could be secured by the use of a steel dilator; the latter must lacerate and leave surfaces ready to absorb septic matter, while you have not the advantage of the presence of the salicylic acid or other disinfectant present in the tent; the latter, expanding slowly, is not likely to cause laceration. The too early removal of the tent, while the spongioles are fast in the uterine tissue, may leave an abraded surface, but after forty-eight hours the tissues have shrunk away and the sponge comes away easily.

Dr. Smith read the following letter from Dr. Mundé:—

"My Dear Doctor:— * * * *

"Remembering your remark with regard to the absence of proper dilatation of tupelo-tents, I procured a number from Tiemann & Co., and dilated them in tepid water. I send you by this same post four different sizes, dilated and undilated, and also two perforated, zinc-lined tents—to be worn during the period, for dysmenorrhœa—one before the other after dilatation.

"This amount of dilatation was reached within one hour. Certainly no fault can be found with the expansion of these tents, since it will be seen, on comparison, that all the tents have swelled to fully double their compressed size and have retained their expansion on being dried. It may be objected that this full dilatation would probably not take place if a resistance were offered, as in the uterine canal. While I partly admit this, still I have, within a month, had reason to use the largest size, to dilate a uterus, and secured quite as much expansion as shown by the accompanying tent. The softness of the wood allows of their being whittled to any size and shape.

"I also send a tent dilated in utero, which shows some contraction at the site of the internal os.

"I presume that the failure of your tents to dilate may have been due to their having absorbed moisture from the atmosphere. They should always be kept wrapped in air and water-tight paper. Tiemann & Co. tell me that all their tents are compressed to their utmost by machinery.

"As for the other forms of dilatation, I have used the steel two-branched dilator of Ellinger, almost exclusively: I found it too difficult to force the graduated hard rubber sounds through the cervix, if it is virginal and hard; the tenaculum tears out and the force is too great. I have dilated in hospital and private practice (with two-branched dilators) in about one hundred and fifty different cases, probably some six to seven hundred times, chiefly for dysmenorrhœa and sterility, always in my office or dispensary. I have almost invariably relieved the dysmenorrhœa, temporarily at least, the sterility but rarely, although my later statistics on this point are meagre. I have but one bad result, pelvic peritonitis, and then curetting and tincture of iodine to the endometrium were also employed, either of which might be blamed. I prefer steel divergent dilators for temporary, tupelo-tents for permanent results. Slippery-elm tents dilate but little, but I have found them good in dysmenorrhœa, to render the canal patent."

Dr. R. P. Harris is using cylindrical sponge-tents, coated with salicylic acid, and finds that they have a local anæsthetic effect on the lining membrane of the uterus.

Dr. A. H. Smith, of the steel dilators which he has tried, prefers the instrument devised by Dr. T. G. Thomas, in which the blades are separated by being drawn into a canula by screw action. It is, however, difficult to clean. He has found the handles of Dr. Elwood Wilson's dilators very much in the way when the uterus is anteflexed.

Dr. Baer remarked that he was much in-

structed by Dr. Smith's remarks. He was surprised at the time—forty-eight hours—that a sponge-tent could be allowed to remain, and its effect in the disintegration of abnormal tissue without the development of the septicæmia. He finds it hard to believe a change could ensue after the uterine walls had been changed to hard, fibrous tissue; but experience is the best teacher.

PHILADELPHIA LARYNGOLOGICAL SOCIETY.

Reported for the MEDICAL AND SURGICAL REPORTER, by Dr. George T. McCracken, Sec'y.

Stated meeting, held Friday, January 27th, 1882, Dr. Cohen in the chair.

Dr. McCracken exhibited a case of Bilateral Paralysis of the Abductors, of which he gave the following history:—

F. G., aged 30 years, marble polisher, had chancre in 1871. Six or seven weeks after had typhoid fever, from which he made a good recovery, and felt well until the fall of 1876, when he caught cold. Since then he has had cough, with muco-purulent expectoration; has lost flesh, especially during the years 1878 and 9, but since that time has held his own. In the winter of 1878 and 9 he first noticed hoarseness, but without any soreness or pain in the throat. Difficulty in breathing commenced in May, 1880, and has steadily increased up to the present time. He has never had any secondary or tertiary manifestations of syphilis, and never complained of headache.

Present condition.—He has cough, with white, tough expectoration; there is inspiratory stridor, which is hardly noticeable when he is sitting, but the least exertion makes it very marked. There is evidence of old trouble at the left apex. On inspection, the epiglottis is found to be somewhat bound down on the left side by an old cicatrix. The vocal cords are reddened and thickened, and the chink between them is about $\frac{1}{8}$ inch in width. In the act of vocalization the cords approximate, but during inspiration they do not move, and on deep inspiration, when the stridor is well marked, the cords retain the same position and are seen to vibrate.

Diagnosis.—Bilateral paralysis of the abductor muscles of the vocal cords, due probably to syphilitic disease of the brain.

In the discussion of this case Dr. Cohen said that the case was interesting on account of the presence of local and central lesions in the same organ, and was probably unique.

Dr. Potsdamer then read the paper of the evening, "A Case of Papilloma on the Right Vocal Cord, followed by Acute Phthisis."

In the discussion which followed Dr. Cohen said that he remembered the patient, and that she had had two attacks of what Charcot calls laryngeal vertigo.

Dr. Cohen then read Dr. A. W. McCoy's, "Report of a Case of Idiopathic Retro-pharyngeal Abscess." (See page 313.)

On motion it was decided to treat this paper as though presented by a member of the Society, and in the discussion which followed, Dr. McCracken related a case of retro-pharyngeal abscess due to disease of the body of the cervical vertebræ, in which the swelling in the pharynx occupied the entire right half, being limited by the posterior palatine arch and the median line of the throat, and in which there was an external fluctuating swelling.

Dr. Sajous related the history of a case which had come under his notice, and in which he believes the retro-pharyngeal abscess to have been of idiopathic origin. The swelling was to one side of the pharynx.

After a private session the rough minutes were read and approved, and the Society adjourned.

IOWA STATE MEDICAL SOCIETY.

Reported for the MEDICAL AND SURGICAL REPORTER, by the Secretary.

This Society met in its Thirtieth Annual Session, at Des Moines, January 25th–27th, 1882. The meeting was called to order at 10 A.M. by the President, T. J. Caldwell, of Adel, and was opened with prayer by Bishop John F. Hurst, D.D.

The following officers were present at the opening of the session: President, T. J. Caldwell, Adel; First Vice President, D. Scofield, Washington; Secretary, J. F. Kennedy, Des Moines; Assistant Secretary, L. C. Swift, Des Moines; Treasurer, G. R. Skinner, Cedar Rapids.

President Caldwell delivered his annual address at 2 P.M., to a large assemblage of the members. It was eminently practical, and he advocated preventive as well as therapeutic measures as the duty of the physician; and when the cause of sickness was ascertained it should be pointed out, and if preventable, removed. He pointed out the importance, as a sanitary measure, of sewerage and drainage, and as a means of proper diagnosis, the use of the microscope. He also spoke of the importance of our annual gatherings being made of more practical advantage professionally.

The following papers were read during the progress of the sessions:—

Dr. A. Reynold, of Independence, on the "Plea of Insanity."

Dr. J. A. Blanchard, of Des Moines, on "Inversion of the Uterus," detailing a case, with the method of relieving it, and giving an interesting epitome of the literature of the subject.

Following this was a good, practical paper by Dr. J. Williamson, of Ottumwa, upon the "Disappointments of Country Physicians in the Practice of Gynæcology." The basis of his remarks was a case of ovariotomy that he had performed and that resulted fatally. The Doctor was led to think that with better sanitary surroundings, better nursing, and the more constant attendance of the physician, a different result might be obtained. The papers elicited quite a good deal of interest, and called out a free discussion, participated in by Drs. Peck, Robinson, of Cedar Falls, Simonton and others.

Dr. R. J. Farquharson, of Des Moines, Secretary of the State Board of Health, read a paper entitled "A Smallpox Hospital." The Doctor gave in detail the plan and specifications of a smallpox hospital erected under his supervision, at Davenport, combining neatness, adaptability and economy. The entire cost was $2500. An animated discussion arose relative to the treat-

ment of smallpox, its prevention by vaccination, the particular advantage of such buildings as Dr. Farquharson constructed; and allusion was also made to M. Pasteur's experiments regarding the prevention of hog and chicken cholera by inoculation, as detailed by him in his remarkable paper read before the International Congress, at London.

A resolution was presented by the Secretary, adopted by the Dubuque Medical Society, regarding the care of the so-called "incurable insane."

Dr. M. W. Stone, of Wahoo, Neb., President of the Nebraska State Medical Society, was introduced by the President, and the courtesies of the Society extended him.

A paper on "Pyelitis Occurring During the Puerperal State" was read by Dr. L. C. Swift, of Des Moines.

After giving some cases, the Doctor emphasized particularly the advantages of the microscope in diagnosing this condition. It was discussed by Drs. Angear, Simonton, Robinson, Hazen and Carpenter.

Dr. Wm. Watson, of Dubuque, presented, through Dr. B. McCluer, a paper on "The Diseases Incident to Military Prisons, and the Influences by which they are Modified." The paper gave the result of his observations while Post Surgeon in charge of Confederate Prisoners, on Rock Island, and embraced several thousand cases. The paper was received, and owing to the absence of the author was read by title and referred to the Committee on Publication.

Dr. G. W. Beggs, of Sioux City, read a brief, pointed, practical paper on the "Management of the Newly-born Infant." He emphasized particularly the importance of wrapping the babe, as soon as it was born, in soft flannel, without washing, and letting it remain in that condition for ten or twelve hours. He believed the pressure to which it had been subjected in utero should be kept up for some time at least after birth, and hence advised the wrapping.

Dr. C. M. Hobby, of Iowa City, presented a paper on "Operative Procedure in Corneal Lesions," which was discussed by Dr. Young, of Burlington, and Dr. Blanchard. It was referred to the Committee on Publication.

"Life—What Is It?" Was the subject of a paper read by Dr. J. R. Gorrell, of Newton.

A paper on the "Local Treatment of the Mucous Membranes" was presented by Dr. E. H. Hazen, of Davenport.

The second evening of the session was occupied by the Section on "Microscopy." Dr. J. J. M. Angear, of Fort Madison, exhibited a number of microscopes, and illustrated, by well selected mounted specimens, the power as well as the beauty of this wonderful aid in diagnosis and in pathology. He gave also an entertaining talk upon Microscopy. Dr. McIntosh, of Chicago, who was present, made some striking and brilliant exhibitions of the power of the Solar Microscope.

The Woman's Christian Temperance Union presented a Memorial asking the Society to appoint from its number a Committee, to prepare a paper or pamphlet embodying the views of the Society upon the use and abuse of Alcohol. The Society thought it impracticable to comply with the request, but passed a resolution expressing sympathy with their cause, and commending the virtues they are striving to teach.

Thomas Dunn English, M.D., LL.D., of Newark, New Jersey, was introduced, and invited to participate in the exercises of the various sessions.

The Committee on Nominations made their Report, which was adopted.

Dr. C. M. Drumeler, of Panora, read, by request, a voluntary paper on "Fracture of the Skull."

All the foregoing papers, after being discussed more or less, were referred to the Committee on Publication.

The Treasurer reported a balance in his hands, after all bills of this session, of $1847.60, and the annual dues were reduced to one dollar per member.

After passing the usual complimentary resolutions and thanks for special favors, the Society adjourned to meet at Council Bluffs, on the third Wednesday in May, 1883.

Editorial Department.

Periscope.

Floating Kidney.

Dr. Landau, of Berlin, has written a monograph on this subject, from which the *Medical Times and Gazette* makes a long extract, the salient points of which we take. A movable kidney is noticed about once in a thousand necropsies. To get at the causation, one must consider the anatomy of the parts, particularly on the right side, and the especial risks and liabilities of women who have borne children. The kidney lies in a nest; it is a retro-peritoneal organ, receiving no true ligamentous fold from the serous covering of the abdomen, but kept in its place by the short and direct course, as well as mesial insertion, of its blood vessels, and by sub-peritoneal connective tissue on its upper surface, and a considerable bed of fat on its external and under surfaces. The anatomical causes of floating kidney may be briefly enumerated as follows: disappearance of the fat about the kidney, and consequent loosening of the peritoneum, especially rapid disappearance, as in acute fevers and acute phthisis; relaxation of the abdominal walls after pregnancy, or in consequence of large ovarian or other pelvic tumors;

prolapse of pelvic organs; tumors of the suprarenal and pancreas, and of the kidney itself. Among the physical causes are direct blows or injuries or repeated strains; coughing, especially where there is wasting of fat; tight lacing. The reason for the greater frequency of movable kidney on the right side, is because the right kidney is less closely and firmly fixed to the back wall of the abdomen, by the hepatic flexure of the colon than the left is by the splenic flexure. The important symptoms are caused by the traction or compression by the kidney, acting as a foreign body, upon nerves, vessels, and the viscera, and by functional disturbances. Hypochondria is frequently observed, especially if the movements be palpable and constantly attracting notice. Hysteria is not uncommon. Circumscribed neuralgias, often flying about, and appearing even in the intercostal spaces, or on the opposite side of the body. The symptoms referable to the great vessels are rare, but œdema of the lower extremity of the affected side, from pressure on the vena cava, has been observed.

Disturbances of the digestive system vary, from slight dyspeptic pains to sickness, chronic catarrh, jaundice, and even to attacks like peritonitis. The movable kidney may become incarcerated (hernia) or twisted upon its axis; an accident which produces sudden symptoms, a sharp pain, followed by tenderness of the whole abdomen, giddiness, cold sweat, small pulse, shallow breathing. Sometimes there is nausea and frequent vomiting; the urine is dark and scanty, and may be mixed with blood; there may or may not be a shivering attack, and fever may be slight. The threatening symptoms reach their height from the fourth to the sixth day; recovery is marked by the excretion of copious, clear urine, of low specific gravity. The prognosis is favorable, and the author does not advocate the practice of extirpating the floating kidney. The operation appears to have been done six times, with an immediately fatal result in three of the cases. As in displacements of the uterus, and in hernia, the principle of treatment is to replace the organ, and, if possible, to keep it in its place. The latter indication is, of course, the chief difficulty, and the author says that a great number of complicated appliances have been devised to that end.

Contagious Pneumonia.

We have twice this year referred to this question, and we have now a third instance to offer.

Dr. W. A. Patchett, in the *Lancet*, says: Four brothers and a sister, all unmarried, lived together; they kept a farm, and had lived together at the house all their life. The house was well and healthily situated, on a steep hillside, and all the sanitary surroundings, ventilation and water supply, were everything that could be desired, so that there could be no suspicion of any septic epidemic pneumonia, or of pneumonia from blood poisoning. The previous health of each of them had been exceptionally good; in fact, they did not remember having had any illness previously.

On January 13th, 1876, I was called to James S., aged seventy-three, the eldest of the family. I found him suffering from typical pneumonia, with crepitation over the front and consolidation of the base of the right lung, a temperature of 104.4° F., a flushed and dusky face, a pungently hot skin, short, hacking cough, with rusty-colored sputa. He had been ailing for three days, and began with shivering and pain in the side. The constitutional symptoms did not appear very urgent, but he rapidly got worse, and died on the 16th, or six days from the commencement of his illness.

On the morning of the death of James S., John S., aged sixty-six, who the day before had complained of rigors, complained of pain in the right side, and cough, with rusty sputa. He was found to be suffering from right pneumonia, which the following day had extended to the left lung. He also did not appear to suffer much, but he said he should not get better. The disease assumed an asthenic form, and he quickly sank, and died on the 19th, or in three days.

On the morning of the 20th Joseph S., aged sixty-three, complained of pain in the left chest, cough, with rusty sputa, and on examination, there was crepitation over the front of both lungs, and dullness over both bases; temperature 104°. The day before he had felt quite well, and was following his usual work about the farm.

On the evening of the 20th W. S., aged sixty-four, on going to bed complained of shivering and feeling cold, and the next morning, on my visit, he was found to be suffering from double pneumonia. In neither of these last two cases did the symptoms appear very urgent, but they were both very despondent, and had a presentiment that they would die the next day; and they did die on the evening of the 22d.

Miss S., the sister, aged sixty-one, had been in attendance on all her brothers during their illness, and she seemed to keep up her strength and health remarkably well; but on the 23d she was seized with right pneumonia, and she quickly sank, and died on January 26th.

As may be imagined, these cases created a profound sensation in the neighborhood, the popular opinion being that, as the brothers and sister had lived so affectionately together all their lives, the death of the eldest had so affected the others that they died "broken-hearted." Dr. Howard (who saw the cases daily with me) and myself were quite unable to explain such an occurrence. When the second brother sickened and died of pneumonia, we thought it was only a coincidence, and that probably nervous shock, caused by the death of his brother, had contributed to his death; but when the remainder of the family sickened and died, of a disease hitherto considered non-contagious, it seemed to point to something more than coincidence merely.

Vaccino-Tuberculosis and Vaccino-Syphilis.

Dr. J. Cappie Shand, commenting on this subject, in the *Medical Press and Circular*, says:—

A paper was recently read by Dr. Wolffe, at the Glasgow Medico-Chirurgical Society, in which he described a case of tuberculosis affecting the eye. He pointed out that a small particle of the tuberculous mass having detached itself,

gravitated through the clear fluid, and itself became the centre of tubercular development.

I would call attention to the fact that this case is of great importance in visually establishing the truth of the danger of transmitting that disease through the medium of vaccination from one individual to another. Moreover, as it is quite a recognized fact that local tubercle is developed by local inflammation, especially in the subject predisposed to tuberculosis, and bearing in mind that vaccination is a local inflammatory process, it becomes clear that a probability almost amounting to a certainty exists, that tubercle may be introduced to the previously healthy individual, through vaccination. Hence, it is necessary, before we take lymph from one infant to inoculate another, to examine, not only the condition of that infant, but also to inquire into its family history, which is practically impossible. Every one knows that an apparently healthy child may be tubercular, but this also applies to other diseases, notably to syphilis, and I may shortly substantiate my statement by recording the following case:—

Three years ago I was in attendance on the widow of a clergyman for a severely ulcerated leg. It did not look syphilitic, but as it would not yield to ordinary remedies, I afterwards used successfully the green iodide of mercury. I then obtained the further information that a child of hers contracted syphilis "through a wet nurse," and after the discharge of the latter the lady had a chancre on her mouth, the result of which I have just mentioned. This boy, however, although having an occasional rash, looked so healthy that one of our first medical men, who was then attending, expressed his urgent desire to obtain lymph from the child after being vaccinated.

All I have to say in favor of animal rather than humanized lymph is, that a breeder of cattle selects for breeding purposes those cattle which he considers healthy and free from disease, and consequently, I would expect greater immunity from hereditary disease among them.

I think syphilis may frequently be produced, as well as tubercle, and remain in the system for a length of time before being recognized; and I am further of opinion, with reference to vaccination, that it should be optional, although apparently desirable, and that it should be put upon such a footing as to prevent it from propagating such diseases as tuberculosis and syphilis.

Treatment of Pemphigus.

Dr. Charles Kennedy contributes to the *British Medical Journal* the following case and notes:—

A. C., aged 23, a shepherd, was admitted to the Royal Infirmary on December 5th, 1881. He was in good condition, and felt perfectly well, except for the annoyance of the skin eruption. His family history was good, and his circumstances comfortable; but he was often exposed to cold and wet in his occupation. The eruption covered the whole body, and had begun to appear a week before admission, in the form of red spots, on which bullæ soon formed and became rapidly larger, varying in size from a pea to a hen's egg. The bullæ were at first clear, but in a day or two became opaque, and then burst, leaving excoriated surfaces, on which crusts formed. The patient was put to bed, and a layer of cotton-wool was put under the back, to keep the raw surfaces left from being rubbed. In order to soften the crusts which had formed over the rest of the body, a little vaseline was applied to them. The bullæ were punctured at the most depending part, the serum which they contained allowed to escape, and care taken that the raised epidermis was laid down flat on the derma, so as to form a complete covering for it. Around the bullæ, which had become opaque, and their contents puriform, there was a ring of inflammatory redness and a good deal of irritation; but when they were punctured while the contained serum was still clear, there was no such irritation, new epidermis formed beneath, quickly, and little or no discoloration of skin remained. The last crop of blebs appeared about a week after the patient was admitted; and a week later he was dismissed, quite better, with only a few blains on the site of the bullæ, which had been followed by crusts. No internal treatment by arsenic or other drug was adopted, no medicine being given except a laxative; and the patient was put upon ordinary diet.

At the clinical lecture on the case, Professor Maclagan stated, as the result of his experience, that acute pemphigus in a healthy subject, as in the present instance, needed nothing but local treatment, as described above, which opinion was confirmed by the result of the case; that in chronic pemphigus, as in other forms of skin disease, arsenic was useful; and that in pemphigus foliaceus neither arsenic nor any other treatment was of real avail.

Ergot in Visceral Atony.

In the course of a concluding article on the Physiological and Therapeutical Action of Ergot, in the New York *Medical Journal and Obstetrical Review*, Dr. Etienne Evetzky makes the following observations:—

"There are a large number of diseases, the essential feature of which is defective innervation of the organic muscular tissue entering into the composition of a given organ. Although in some cases this relaxed state is a secondary result of inflammatory action in the part itself, in the majority of cases we have to deal with primary atony and deficient innervation. Whatever may be the ultimate pathology in any given case, the usual practice consists in the use of various excito-motors, such as strychnia, electricity, douches, massage, etc. Considering that stimulation of the organic motor centres forms the most essential part of the physiological action of ergot, it is rather surprising that it is not used more commonly in these cases, particularly as ergot is superior to any other excito motor." He then notes the following disordered conditions: Atony of the stomach. When no definite disease exists, atonic dyspepsia is often due to a loss of power or tonicity on the part of the stomach. So also, in dilatation of the stomach, which is due in a marked degree to a paresis, from insufficient motor innervation, and is analogous to the uterine relaxation immediately after labor,

ergot will prove beneficial. Atony of the intestines. Manifested mainly by constipation, and brought about by irregular habits and sedentary life. Curran has succeeded in overcoming the torpidity of the bowels in paralytics with ergot, when the most energetic purgatives had failed to act. Its power of causing and increasing peristalsis can be verified by the reader; let him take a full dose of the fluid extract of ergot, and within half an hour he will notice the effects, varying from perceptible peristalsis to the actual inclination on the part of the bowels to move. Atony of the anal sphincters, which determines prolapse of the rectum, has been frequently relieved by hypodermic injections of ergotin, half a grain, in the vicinity of the anus, every few days, the parts being held in normal position by mechanical support. It has also been found useful in paralysis of the anal sphincter after parturition.

Langenbeck has obtained good results from its hypodermic use in invagination of the rectum. Two cases are reported of strangulated hernia readily reducible after hypodermic injections, that had resisted all mechanical efforts. Atony of the bladder, secondary to a diseased state of the spinal cord, or due to some functional disorder of its innervation, invariably yields to ergot. Sutton used it with marked benefit in the retention of urine during grave constitutional diseases, while Sorbet cured a case of incontinence of fifteen years' duration in eleven days. Malarial enlargements of the spleen yield rapidly to its influence. It will control excessive mucous or muco-purulent discharge. Ergot promptly checks excessive flow of milk, and is capable of suppressing it entirely. Diabetes insipidus, which is due to paresis of the renal vaso-motor apparatus, is almost always cured by ergot, while diabetes mellitus is often favorably influenced by it. Albuminuria and its accompanying symptoms have been temporarily benefited by it. Spermatorrhœa and prostatorrhœa, are much benefited by ergot in connection with sedative and tonic treatment. It has been found useful in diarrhœa and dysentery. It will relieve cerebral hyperæmia, and has furnished good results in epilepsy, sunstroke, and the various vaso-motor neuroses. When neuralgia depends upon vascular disorders of the nerve sheaths, ergot is very frequently of great benefit. Chevallereau administered a hypodermic injection of ergotin to a rheumatic patient to stop a hemorrhage; it acted also so well on the rheumatic symptoms that he persisted in this treatment, and used it in two other cases. In all these three patients the benefit was very striking.

Hypodermic Injections of Sulphuric Ether.

Dr. L. E. Dupuy has published a very interesting article, continued in several numbers of the *Progrès Médical*, on "Subcutaneous Injections of Sulphuric Ether Applied to the Treatment of Cholera during the algid period." We have room but for the following brief extracts, which, however, embody his principal conclusions. He first considers the hypodermic use of ether from a general point of view, and cites very fully all the authorities on the subject. In adynamic forms of typhoid fevers, pure ether under the skin has given good results; the pulse rapidly gains both fullness and strength; the heart beats, at first hardly perceptible, become more distinct; often, after one or two injections, cyanosis and collapse disappear, and the patient awakens from a condition which was considered desperate. Soon after an injection the patient may experience a local sensation comparable to that produced by an application of Mayor's hammer. There are many cases on record, however, in which the injections were equally effective, and yet have produced no local irritation.

In a case of profuse hemorrhage following labor, the patient was in a state of collapse. Three syringefuls at short intervals brought a rapid and favorable change. In a state of coma following copious hemorrhage, from the extraction of a naso-pharyngeal polypus, forty drops of ether hypodermically caused a rise in the temperature, which had fallen to 92.30° Fahr., and brought the youthful patient within the usual conditions attending surgical cases.

Ether, hypodermically injected, is rapidly absorbed; its effects become perceptible on the pulse after a very few minutes. The lungs will eliminate ether in ten to thirty minutes after an injection of from one-half to three-quarters of a drachm. It acts as a stimulant of the heart, and increases the frequency and energy of arterial pulsation. It revives the central organ, even when the cardiac muscle contracts but very feebly.

From experiments made upon animals, it would appear that injections of ether may be of benefit in cases of poisoning when the heart is feeble, and the pulse imperceptible.

Injections of ether cause a slight rise in temperature, something less than a degree. Our experiments warrant the observation that "the rise in temperature following ether hypodermically is the greater, in proportion as the central temperature was lower prior to the injections."

When temperature is less than normal, ether will determine a rise of one or more degrees, but its effects are only transitory; to maintain them, injections must be continued at regular intervals.

Owing to the rapidity with which ether is absorbed by the blood, its effects on the nervous system are stimulating, so long as it is administered within the limits already indicated; larger doses, and prolonged action of the remedy will be followed by resolution and anæsthesia.

Ether hypodermically is not only of benefit in cases of collapse following hemorrhages, or to individuals enfeebled by various causes; it has a direct effect on the total adynamia attending miasmatic diseases.

The effects of ether on the urinary secretions have not, as yet, been satisfactorily ascertained.

Dr. Dupuy devotes the second part of his paper to the treatment of cholera during the algid period. He admits that no specific has, as yet, been found in this disease. He says: In the algid period the pulse increases in frequency, becomes small, filiform, and very depressible; it becomes imperceptible at the radial, and progressively disappears from the humeral, crural, and finally, from the carotid arteries. The dis-

appearance of the pulse beats is considered a very grave omen, especially if it continues for some time. The heart becomes adynamic. Authorities differ as to the causes; but it is certain that an energetic excitant, acting rapidly upon the heart, through the agency of the nervous system, must prove efficient against the effects of cholera poison. Sulphuric ether, as has already been observed, seems to supply the requisites here indicated, and its rapid action upon the heart and the circulation must render important service in the treatment of cholera in the algid period.

The most serious cases of cholera are those in which there is a considerable fall in central temperature. We have reference to rectal temperature, as in cholera the axilla is an unreliable guide. A fall of one degree in rectal temperature should be looked upon as a grave symptom.

We hope we have satisfactorily proven that ether injections can produce a rise in temperature, and that this elevation is in proportion to the existing prior depression.

The following are the requisites in cholera algidity: rectal temperature, which in serious cases falls one or more degrees below, must be brought back to the normal point. This elevation should be rapidly obtained, because the disease makes rapid progress. It is equally important to be able to stop when desired, and only exercise a temporary effect on the temperature, because sudden hyperthermia is to be guarded against. From a theoretical point of view, ether injections seem to supply all these desiderata. We have had occasion to test their good effects in two cases, and believe them beneficial in all adynamic forms in which active stimulation of the nervous system is necessary.

It has been claimed that during the algid period in cholera absorption ceases, and medicinal substances remain without effect. This does not apply to the hypodermic use of ether. We have every reason to believe that the highly diffusible nature of this substance renders it particularly well fitted for the purpose for which it is recommended.

Physiological and Therapeutic Effects of Phosphorus.

The *Revue Médicale* states that M. Du Moulin recently read before the Medical Academy of Belgium some observations made on a case of poisoning by phosphorus, showing that the presence of this substance can be readily ascertained, notwithstanding the denials of the patient, and although but a small quantity may have been taken. The secretions revealed unexpected perturbations. Not only had the urine become icteric, but it was alkaline, and albuminous, and had, moreover, almost entirely parted with its earthy salts. Its density was reduced to 1.006, and the quantity of urea had fallen much below the normal. The urine also contained leucin and tyrosin. The stools were discolored (icteric) and mixed with blood. The perspiration was alkaline, as were also the matters vomited (these were a mixture of mucus and gastric juice). On the other hand, the saliva was strongly acid, but the laryngeal secretions had remained alkaline.

Essence of turpentine was given at different times, and invariably thrown up as soon as taken. A chlorate of potash gargle was then given, to counteract the buccal inflammation, but the patient swallowed the greater part of the solution. Finding that considerable improvement appeared to follow, and remembering that M. Huseman had recommended chlorate of potash in case of poisoning from phosphorus, the salt was continued, and in a few days the patient was convalescent.

Without positively asserting that this cure was due to chlorate of potash, M. Du Moulin believed that in similar cases it would be advisable to use this remedy, either alone or in combination with turpentine, should the patient be able to tolerate this latter.

Treatment of Epilepsy.

M. Ball, the present professor of mental diseases at the Paris School of Medicine, considers that the drugs most used in epilepsy prove much more efficacious when taken in combination with each other, than when one of them is administered singly. The alkaline bromides, particularly the bromide of ammonium, with belladonna and oxide of zinc, form the basis of treatment.

The following solution may be given, in tablespoonful doses:—

℞.	Ammonii bromid.,	℥ iiss	
	Sodii bromid.,	℥ iiss	
	Aquæ destil.,	f℥ x.	M.

At the commencement of treatment four tablespoonfuls of this solution may be taken during the day, and the dose increased to eight or ten tablespoonfuls if no appreciable effect is noticed after a few days.

Belladonna and oxide of zinc are administered in pill form, as follows:—

℞.	Ext. belladonnæ,	gr. xv	
	Zinci oxid.,	gr. xv.	M.
	Ft. pil. xl.		

Sig.—One pill may be taken in the morning, another in the evening, at first; then the dose may be increased to four pills per diem.

If any degree of plethora exists the drastic purgatives should be resorted to, and in some cases benefit is obtained from a general bleeding, or the application of leeches to the temples or behind the ears.

M. Ball gives the following formula for drastic pills:—

℞.	Aloes,	gr. xv	
	Scammon. resin,	gr. viiss	
	Jalapæ resin,	gr. viiss	
	Calomel.,	gr. viiss	
	Saponis medic.,	q. s.	M.
	Ft. pil. xxiv.		

Sig.—These pills are to be taken once a week, three in the morning and as many more about noonday.

What is of importance to notice is the immediate beneficial effect of this combined treatment; this is sometimes remarked on the second day.

This method, like all other forms of treatment of epilepsy, should be continued for a long period, and should not be suddenly stopped; the doses should be progressively and slowly diminished when it is considered safe to lay aside the treatment.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

WHEN SHOULD CHILDREN BE SENT TO SCHOOL?

The old-time family physician, in his dual capacity, of healer of ills and general father confessor and adviser of his life-long patients, will frequently have this question propounded to him. Many parents will ask his advice on this subject; and it is a point that is worthy of more careful consideration than most persons stop to realize. In a country like ours, where the public school system is so universal that even the very poorest classes can afford to give their children some education, the temptation to send the little ones to school prematurely is very great. By so doing their minds are trained, and what is a great consideration to many parents, they get them "*out of the way*" for a goodly portion of each day. But we must ever realize that during very early life all the forces and energies of nature are required to enable the child to grow and develop physically, and that if this power be diverted from its natural channel to assist the premature development of the mind, the bodily or physical system will be apt to suffer for the want of it. We have no doubt that the most perfect adult, physically and mentally, would be produced, were the pre-puberty period of life devoted almost entirely to physical development, the mind receiving only the inductive training of example from intelligent and refined home influence, and if active school life was not allowed until this period. This plan would bring educated men out from their colleges to mix with and battle against the world at a more advanced age than is now the rule; but this would be all the better, since the whole being would be more mature and much more capable of meeting and successfully mastering the exigencies of life.

Since, however, this idea is opposed to the popular sentiment of our country, it becomes impracticable. But a modification of it will prove a great improvement on the present plan. When a physician is consulted about sending a child to school, he must take into consideration several points in making up his opinion. Does the child inherit any tendency to disease? If it does, this tendency will be fostered by the confinement of school life. Is the child of a nervous or a timid temperament. If so, the rough handling it will receive, and the worry over excessive desire to excel in study, so common to nervous temperaments, will prove injurious. Does the boy or girl evince a desire to study? If not, the necessary *driving* will be injurious. Is he well advanced, *physically*, for his age? If *yes*, then attendance upon school will do him no harm; if *no*, then he had better run wild for a year or two longer. If he is vigorous, and yet unruly and uncontrollable, then may school discipline correct these faults. If he is gentle and docile, and not notably hearty, with a slight tendency toward a scrofulous or lymphatic temperament, then will it be better to postpone his mental training for a time. The valuable lessons of *self-control* will not be so much needed by such a disposition as by one who is wild and self-willed. It would be well to inquire most searchingly into the ancestral history of a child before concluding. Because we all know that a tendency to disease may be inherited, and yet by

careful hygienic surroundings and conditions may be aborted, while bad sanitary conditions may foster and develop this latent tendency in its most virulent form. Therefore, in conclusion, after having considered all the points bearing on the case, ask yourself the question, "*Can the confinement and mental labor incident to school life* POSSIBLY *injure or retard this child's physical development?*" If your judgment answers in the affirmative or leaves any room for doubt, give the benefit of the doubt to the body, and advise against school. But if the reply is unquestionably negative, then you can safely advise school.

MEDICAL SCIENCE.

The publication and sale of books devoted to routine rules of practice, and volumes containing the favorite prescriptions of prominent physicians, would tend to make one think that there are certain doctors who practice medicine by routine; who will, when called to a sick man, go through a routine examination, according to some text-book direction, and having concluded that he has a certain disease to deal with, will order the formula committed to memory that he understands some great medical light has, at some time or other, used for the same disease. It is but little to be wondered at that such a machine-like doctor fails to cure many cases of severe illness that really require medical interference. His cases that would get well if left alone will sometimes recover under this foolishly empirical treatment, but he will rarely be successful in those cases that have a natural tendency toward dissolution, and can only be checked in their downward course by rational and energetic measures.

The reason is obvious. Medicine is not an exact science. We cannot say, as in arithmetic, that two and two, absolutely and without exception, make four. It is impossible to formulate any definite and universal laws for the alleviation of disease, since in each individual case the disease will present some peculiar phases, dependent upon the external and internal collateral circumstances that may exist.

The distinguished and successful practitioner is he who, with a thorough knowledge of the import and significance of every condition that may present itself, and with an intimate acquaintance with the uses and properties of all the remedial measures we possess, treats symptoms as he finds them. To him, it matters not what name you give to any particular group of symptoms. He does not treat typhoid fever because it is typhoid fever. But if he finds a dangerously high temperature, he endeavors to reduce it. He combats dangerous weakness. He controls diarrhœa. He antagonizes exhausting wakefulness; and thus by constant vigilance, and a reasoning and sensible treatment of symptoms, he manages to keep his patient alive until the forces of nature can effect the cure. Therefore will it be well for every physician who loves his profession and desires to be successful in its practice, to remember and act on this principle, that there are no absolute and universal rules for the treatment of sickness. It might almost be said that no two cases of the same disease will call for precisely the same remedial agents. He must recognize the importance of even the smallest and apparently least significant symptoms. He must be thoroughly acquainted with materia medica and therapeutics, when he can make up his own intelligent line of treatment and will not be compelled to use the antiquated and worn-out thunder of another man's brain.

Notes and Comments.

Hypertrophied Heart.

Dr. Samuel West presented to a recent meeting of the Pathological Society of London (*Lancet*) a case of hypertrophy of the heart, in which the usual causes were absent. The patient, aged forty-one, was well until three months before his admission to the hospital. He then had dyspnœa, pain and palpitation. The heart was found very large, no murmur, the arteries were hard, lungs emphysematous, and there was a small amount of albumen in the urine. Chronic Bright's disease was diagnosed. He became unconscious and died. At the autopsy, the kidneys were congested, but otherwise healthy; there was no sclerosis; the heart weighed twenty ounces, and was very large,

slightly fatty, no disease of valves, and no cause of the hypertrophy, which was confined to the left ventricle, was found. It was, therefore, a case of cardiac hypertrophy, without any of the usual causes being present. It also showed how such a heart may break down, without obvious reason. Dr. West suggested that the coronary arteries did not increase in size in proportion to the size of the heart, and so a point was reached where the blood supply was deficient, and fatty degeneration occurred.

Circumcision—Death.

Mr. F. H. Weekes reports the following case in the *Lancet:* A young man, aged seventeen, was admitted to the hospital with double inguinal suppurating buboes. There was also phimosis of an elongated prepuce, apparently due to the presence of three or four soft sores at the junction of skin and mucous membrane. General health good. Circumcision was performed in such a manner as to remove all sore places. This exposed a healthy glans, and a urethra free from inflammation. After the operation, the patient was comfortable for four days. The temperature did not rise above 98.5°. The wound healed for the most part by granulation, and there was scarcely any swelling of the penis. On the morning of the fifth day the temperature was 99.5°, and in the evening the patient was chilly and had a temperature of 105.4°. On the following morning the temperature was 105.4°; pulse 120, weak; respirations 30. He had been delirious during the night. The penis was slightly swollen and covered with a red blush; but this color faded gradually away, and had no definite margin. The posterior lower two-thirds of the left lung were dull on percussion, and in that region could be heard tubular breathing and broncophony. In the evening temperature was 104.5° although during the afternoon two five-grain doses of quinine had been given. The next morning temperature was 104.5°; pulse 130; respirations 30. He had not been sick, but had taken very little food. There was a dry, brown tongue, and involuntary passage of fæces. During the afternoon the patient became weaker, and died.

Nerve Stretching in Locomotor-Ataxy.

We read in Paris *Médical* as follows: Last year this journal published the results of nerve stretching in locomotor-ataxy, as practiced in Germany, and repeated in France by Debove. The first successes attending this method warranted the belief that a remedy had at last been found for relieving the lightning pains in ataxy, and, indeed, for curing the disease itself. Experience has proven, however, that this method only brings temporary relief, and that but little dependence can be placed on its good effects.

At the congress of German naturalists, held in Saltzburg, in 1881, German and Austrian physicians and surgeons were of opinion that this new method had given but illusory results, and that after an apparent improvement the disease again followed its progressive course.

Moreover, at a recent meeting of the Medical Society of that city, Bernhardt, Leyden, Litten, Goldammer, and Israel have adduced numerous facts dismissing all doubts, and proving that the elongation of the large nerve trunks, in cases of ataxy, may, for a few weeks, abate the lightning pains, restore cutaneous sensibility, and reëstablish equilibrium of motion in the limbs; but soon after the pains return, if not in their original seat, then in belt-like form around the body, and the motive troubles become more than ever aggravated; tactile sensibility alone continues somewhat longer, showing signs of improvement. According to this, it would seem that nerve stretching only awakens hopes in the minds of patients that are doomed to be disappointed.

Carbolic Acid.

At a recent meeting of the Surgical Society of Ireland (*Medical Press and Circular*), a discussion took place concerning the poisonous qualities of the carbolic spray in surgery. Dr. Warner read a paper, in the course of which he pointed out some fatal cases of poisoning from this drug. Mr. W. Thornley Stoker then said, "That he had seen the spray used in hundreds of cases, and never, in any instance, was the slightest symptom of carbolic acid poisoning produced, save one, a case of his own, where the carbolic oil was applied as a dressing to a large superficial burn." He believes that carbolic oil of the usual strength, one to four, is a dangerous agent when applied to burns of a large extent. He had never heard of an authentic case of carbolic acid poisoning (save the one mentioned) in the hospital practice of those around him. Mr. Hamilton stated that at Stevens' Hospital no capital operation—he might almost say no operation at all—was performed without carbolic acid, and so far as his experience went, he had never seen a bad result that could be set down in any degree to the poisonous effects of carbolic acid. Dr. Benson remarked that for two years past they had been using the spray in ophthalmic surgery, in St.

Mark's Hospital; there were only two cases in which operation was followed by suppuration, and in these cases the spray had been accidentally omitted. On the other side, Mr. O'Grady, referring to the alleged diminution of erysipelas from the use of carbolic acid, said he had been sixteen years attached to Mercer's Hospital, and never saw the disease there, except it was imported. His colleagues and himself had given up using carbolic acid, because they did not believe in it. He had seen mischief follow its use. In a case of ovariotomy, two or three days after the operation, while he was injecting an aqueous solution of carbolic acid into the wound, the woman, who was laughing and joking, became suddenly insensible and died in ten minutes. He could not attribute the death to any other cause than carbolic acid. Mr. Corley thought that the unfavorable results sometimes noted might be due to the use of impure acid. He had himself noticed some bad results when he used the ordinary carbolic acid, but had never seen any since he commenced to use absolute phenol, as recommended by Lister.

The weight of evidence in this discussion was in favor of the use of carbolic acid in surgery. That such an argument could occur, would tend to show that there is no absolute certainty about this question, but that, like many other articles in medicine, it may sometimes do harm, and this ought to be borne constantly in mind when using the acid.

Pyæmia from Otitis.

At a recent meeting of the Pathological Society of Dublin, Dr. Walter Smith (*British Medical Journal*) showed the left petrous bone, cerebellum, and lungs of a young man of 21, who had enjoyed good health until December 23d, 1881, when severe pain suddenly set in in the left ear and left side of head. Next day there were rigors, sweating, and vomiting. Was admitted into hospital January 1st. There was no history of any discharge from either of his ears. The temperature ran a completely typical course—on one occasion it fell to 96.7°, on another it rose to 107.4°. There was a similar want of accordance between the pulse and respiration records. There was complete absence of any paralytic symptoms, general or special. The sputum was rusty and streaked with blood, but physical signs of pneumonia were not discovered until January 9th. The cerebral symptoms then became latent. Examination revealed bulging of left membrani tympani, but there was no perforation or otorrhœa. After increasing dyspnœa, death ensued on January 15th. Spleen was found large and pulpy, weighing ten ounces and a half. There was some left pleural effusion; foci of embolic pneumonia were found in the left lung. The right lung was tough, non-crepitant, and in places quite gangrenous, with several softening, embolic pneumonic patches. Necrosis of the pleura was well marked on the surface of the lung. A small, greenish abscess was observed in the cerebellum, below the left corner of the pons varoli. A thrombus lay in the left lateral and superior petrosal sinuses. The left petrous bone was diseased and very fetid. The cavity of the tympanum was full of brown, grumous stuff, and its roof was broken down and perforated.

Operations in Individuals Subject to Erysipelas.

At a recent meeting of the Société de Chirurgie (Feb. 1st) M. Verneuil called the attention of the members to an important subject. In the course of practice, he found himself obliged to operate in three case where the individuals had had one or more attacks of erysipelas; in all three, erysipelas, either spontaneous or surgical, supervened, and the three patients succumbed.

M. Verneuil asks if his colleagues have no analogous observations, and if it would not be proper to consider the prognosis of graver import after operations or severe wounds in individuals who have been more or less subject to erysipelatous attacks.

M. Desprès does not consider that this circumstance aggravates the prognosis; he has operated in four such cases, and erysipelas supervened twice, but did not prove of any exceptional gravity. M. Marc Sée operated in one such case and erysipelas did not supervene, but a case operated by M. Gilette sustained the opinion of M. Verneuil.

In concluding, M. Verneuil, remarked that in the six cases reported by his colleagues, erysipelas appeared three times. It is true, as M. Desprès asserted, erysipelas is rarely fatal when the internal organs, liver, kidneys, lungs and heart are healthy, but under opposite conditions, or when the patient is a drunkard, the prognosis is very grave.

Treatment of Rabies.

At a recent meeting of the Société Méd. des Hôpitaux, of Paris, M. Gingeot remarked that in a case of rabies he had employed the hoangnan, said to be much employed among Eastern nations. He did not observe any beneficial effects from its use, but it was not given until

late period of the malady. He considers that the medicament is best administered hypodermically, using a watery solution of the alcoholic extract, as the pills are swallowed with difficulty and frequently rejected by vomiting.

M. Dujardin-Beaumetz considers the Russian method of treatment the best of those at present known. The patient is placed in an over-heated room and garlic or sulphide of allyl is administered. Six months since he had three persons under his care, who had been bitten by a dog undoubtedly mad; they were submitted to this form of treatment in all its details and escaped without presenting any symptoms of rabies. Valdivine, which has been vaunted in this affection, has proved of no value in his hands.

M. Sévestre said that an attenuation of the symptoms was obtained in one case by the administration of pilocarpine, but the patient finally succumbed.

Kangaroo Tendons.

Mr. T. M. Girdlestone read a paper on the "Surgical Uses of Kangaroo Tendons," before a recent meeting of the Royal Medical and Chirurgical Society (*Medical Times and Gazette*). He stated his belief that for tying large vessels in their continuity, the long, even tendons from the tail of the Kangaroo were as strong as the silk ligature, and caused no ulceration in the coats of the vessels, and had all the valuable qualities of catgut, without its defects. It also makes an excellent suture, resisting the effects of purulent discharges for a long time. They have been used in Melbourne, in place of silk or gut, since 1877. In the deligation of main arteries, the inner coats of a vein could be divided or not, and the ends of the ligature cut off short. A reef knot does not slip nor become loose. When there is no suppuration the tendon coalesces with the tissues, and in suppurating wounds, though softened, they are found to still hold together at the end of eight days. The tendons were previously immersed for some weeks in carbolic oil, and entire tendons only were used. They have been employed in ovariotomy, and in vesico-vaginal fistula, and held till union took place. In plastic operations, hernia and varicocele, the tissues have readily healed over them. A medium-sized tendon is so strong that it is difficult to break it with the hands, and it is uniformly strong throughout its length of from twelve to eighteen inches. They can be hardened for use as sutures by immersion in a half per cent. solution of chromic acid, after which they can be also used as drains for wounds.

Nutrient Suppositories.

Dr. H. E. Spencer thus writes in the *Practitioner:* Artificially digested meat is mixed with a little wax and starch, and made into a suppository. These suppositories are of such a size that the digested and extracted product of twenty ounces of meat from which the insoluble matter is removed is contained in about five suppositories. It is easy for most patients to introduce them themselves; and their use is attended with no discomfort whatever, in the majority of cases. After an hour or two, the waxy basis is frequently returned, the peptone and extractive being absorbed. In some few cases, owing to irritability of the rectum, the whole suppository has returned; but this can be obviated by the addition of a little opium. He has had excellent results from their use in cases of gastric ulcer, stopping all food by the mouth for a fortnight or so, and ordering the patients to insert a suppository every four hours. Great relief was obtained by the same means, in a case of cirrhosis of the liver, where gastric irritation was a prominent symptom. The life of an old lady dying from gastric carcinoma was prolonged for several weeks. An immediate improvement took place as regarded the pain, sickness and prostration, and the patient was enabled to sit up and make her will. It is true that the amount of food administrable in this way is very small, but every practitioner who has had cases of obstinate vomiting under his care knows how minute a quantity of nutriment will "keep body and soul together" for several weeks or months.

Mitral Stenosis.

The thesis of Miss Mary Marshall (*Thèse de Paris*, 1879), inspired by M. Landouzy, is devoted to establish the assertion that mitral stenosis is much more frequent in women than in men, and that in a proportion of two to one. This conclusion is based on statistics compiled from French and English hospital reports.

The causes of mitral stenosis are the same as for other cardiac disease; rheumatism holding the first place; the influence of puerperal diseases is rarely noticed in the observations. To explain the greater frequency of mitral stenosis in females, the author brings forward the anatomical conditions, asserting that this orifice is narrower in women.

Again, it is said that during the child-bearing period the blood is less alkaline in women, and would, therefore, have the same irritating effects observed in rheumatism.

Modern Surgery—Extirpation of the Lungs.

Under this heading the *Medical Press and Circular* says: If the ancient masters of surgery were now to visit some of our modern hospitals, and see the operations therein performed under the protecting shadow of antisepticism, what surprise would they not evince at the daring of modern surgeons! Operations condemned in their day as unjustifiable and hazardous are now recognized standard ones. They would learn with surprise that we remove kidneys, spleens, uteri, portions of intestines, larynx, with perfect *insouciance*. It is even now proposed to extirpate one of the lungs. At a recent meeting of the Biological Society of Paris, M. Marcus (Jassy) suggested an operation for the removal of one of the lungs. M. Marcus believes that, as the lungs are dual, one could be removed; the other would do the work, just as one kidney does the work of two when one has been removed. M. Marcus has put his suggestion to proof. He extirpated the right lung in some rabbits and dogs. In spite of antiseptic precautions, however, they died. The dogs died rapidly; the rabbits lived for three weeks. M. Marcus thinks that his results are encouraging.

Premonitions of Epilepsy.

In the course of an article on epilepsy, in the *Practitioner* for February, Dr. Radcliffe furnishes the following as premonitory symptoms of an epileptic seizure, and the relative frequency with which each has occurred in his own experience:

Involuntary jerkings, startings and spasms	38
Vertigo	34
Unusual craving for food	29
Unusual sleepiness	23
Respiratory pauses, followed by long breaths	20
Hallucinations	12
Nightmare	12
Frequent pertes seminales	12
Rolling of the eyes	5
Grinding of the teeth	4
Palpitation of the heart	4
Headache	3
Tingling or numbness	2

Anæsthesia.

Commenting on the danger of using pure chloroform for anæsthetic purposes, Dr. Henry Smith says, in the *Lancet*, "During the last five years, both in private and hospital practice, the anæsthetic employed in my operations consists either of ether alone, or of the mixture composed of one part alcohol, two of chloroform, and three of ether. This mixture is comparatively harmless, and will produce the same amount of insensibility as is effected by more dangerous anæsthetics."

Special Reports.

NO. V.—OPHTHALMOLOGY.

BY CHAS. S. TURNBULL, M.D.

Effects of Eserine and the Mydriatics, Atropine, Duboisine, Homatropine and Hyoscyamine.

After a series of careful experiments,* Herm. Schäfer (*A. f. Oph.*, Vol. x, No. 2) states, in regard to the influence of eserine upon the three agents, atropine, duboisine, homatropine, that it counteracts the effects of homatropine completely and permanently; that of duboisine, and more particularly that of atropine, however, only when instilled in larger quantities, and then only for a brief period, after which it yields again to the effects of the latter.

The *absorption* into the aqueous humor of these three substances (atr., dub., hom.), as well as their *transmissibility*, has been demonstrated by experiments. Aqueous humor containing atropine and duboisine acts more rapidly when transferred. Aqueous humor containing atropine and duboisine secures maximum dilatation, but that charged with homatropine does not effect this result completely.

In general, it is sufficiently demonstrated that, as respects the *dilatation of the pupil*, atropine, if somewhat slower, possesses a more lasting influence than duboisine; that the latter dilates the pupil in a shorter time, and momentarily acts more energetically, but loses its influence more quickly; finally, that homatropine develops its influence in a briefer time than either of the other agents, but produces a lesser dilatation of the pupillary diameter, and is the first to decline in its effects. The degree of concentration in which the homatropine is employed is apparently without influence upon the duration of the effect.

The *accommodation* is paralyzed more rapidly by duboisine and homatropine—by duboisine even a little more so than by homatropine; with the latter, however, the normal state returns in twenty-four hours, with duboisine after three to four days. Paralysis of the accommodation by atropine proceeds very gradually, and persists the longest.

In accordance therewith would be the *practical application* of these three agents. Where it is desired to secure simply dilatation of the pupil for the purpose of examining the fundus, or to paralyze the accommodation for the certain determination of the state of the refraction, homatropine is decidedly to be preferred to the other drugs.

*Translated by Isidor Furst, M.D., of New York.

Dr. S. D. Risley, in a recent paper,* also concludes "That for the correction of anomalies of refraction in otherwise normal eyes the homatropine is to be preferred."

If, on the other hand, a therapeutical effect is desired, homatropine is to be set aside, on account of its insufficient and too restricted effect, and the application of atropine and duboisine can alone enter into consideration. Risley (*loc. cit.*), from a therapeutic standpoint, concludes "That, if retino-choroidal disturbance is also present, hyoscyamine or duboisine are preferable; (*a*) to atropine, because of the shorter duration of the treatment; (*b*) to homatropine, because of their more persistent control over the ciliary muscle; and that hyoscyamine† is preferable to duboisine, since the tendency to systemic poisoning is not so great."

Schäfer recommends the use of duboisine in iritic conditions, with or without extensive synechiæ, where atropine had been employed for some length of time, and with but partial success, on account of conjunctival and ciliary injection. Duboisine, he says, never causes conjunctival irritation, and even diminishes that caused by atropine.‡

Dr. H. Knapp (*Archiv f. Ophthal.*, Vol. x, No. 2) reports *three cases of quinine amaurosis.* The characteristic features of this affection, according to Roosa, Wecker, Voorhies, Michel, Gruening and Knapp, are:—

1. Total blindness subsequent to the taking of large quantities of quinine.§

2. Pallor of the optic disks.

3. Marked diminution of the retinal blood vessels, in number and calibre.

4. Contraction of the visual field.

K. mentions some *other symptoms:* "1. *Diminution of the color-sense* (red-green, then green blindness); 2. *Diminution of the light-sense* (as if a vail was over the eyes); 3. *The pupils during the total blindness are irresponsive to light*, but (Gruening) move on accommodative efforts; 4. *Anœsthesia of the cornea;* 5. *Impairment of hearing*, to total deafness, and *tinnitus aurium* in every case, *though transient.*"

The subjective noises and deafness, though exceedingly frequent symptoms of quinism, are always transient; I, at least, have not been able to trace one case of persistent deafness or tinnitus aurium to the use of quinine alone. (L. Turnbull has long since emphatically expressed himself in a similar way.—Rep.) The impairment of sight will, I suppose, disappear entirely in the mild cases, whereas in the severe typical ones the restoration of the central acuteness of vision seems to be complete only in a certain number of cases; in almost all, however, a fair amount, $\frac{20}{200}$ to $\frac{20}{20}$ of S., is regained. The contracted visual field expands slowly, commonly does not reach its natural limits again.

The progress of quinine amaurosis, even in advanced cases, is, on the whole, good, as there is, thus far, no case of permanent blindness on record, and the typical, *i. e.*, fully developed cases, are very rare. How frequent the mild cases are, and how rapidly they recover, remains for further investigation to ascertain.

No beneficial mode of treatment seems yet to have been discovered. The "depleting therapy" to which v. Graefe ascribes the recovery in his second case will, in view of the marked ischæmia of the retina discovered of late, scarcely find any advocates now. Nitrite of amyl, given in the way of inhalation, by Voorhies, Gruening and Michel, showed no effect. Strychnia and other remedies, as well as electricity, were likewise inefficient. Horizontal position, as long as the general anæmia, and particularly that of the brain and eye, are marked, seems beneficial. Generous diet, with perhaps gentle stimulants, and as soon as practicable, sojourn and exercise in a healthy, invigorating atmosphere, appear rational means of recovering strength, and supplying the retina with what it most needs—blood."

Dr. J. J. Chisholm, of Baltimore, at the last meeting of the Am. Med. Association, read a paper on the *Actual Cautery Needle in the Treatment of Conical Cornea.* The operation is performed with a fine sewing needle, heated to whiteness in an alcohol lamp, and thrust through the apex of the cone. The subsequent cicatrization causes a flattening of the cone. Dr. C. also exhibited a *needle designed for the destruction of the hair-bulbs*, in cases of displaced cilia, by electrolysis. It consists of a needle set into a handle, which is introduced *cold* into the root of the hair-bulb. By pressing on a button, connection is made, and the needle becomes heated, and the electrolytic action is manifest by the bubbles of gas escaping. Reported (*A. f. O.*, Vol. x, No. 2, by S. Burnett, M. D.)

In his abstract of *Am. Ophthal. Literature* for the first quarter of the year 1881, Dr. Swan M. Burnett, of Washington (*loc. cit.* p. 235), reports the following:—

* "The Comparative Value of the Mydriatics," Transac. Am. Ophthal. Soc., 1881.

† Hyoscyamine grs. ij to f℥j. R. fears they adulterate Hyos. with Atrop.

‡ We cordially endorse Shäfer's recommendation of duboisine in iritic conditions.

§ The *total blindness*, in all the cases thus far made known, was only temporary.

H. M. Bannister. *On Some Points in Regard to Color Blindness.* (*Jnl. of Nervous and Mental Diseases*, Jan.) B. takes the same position as the reviewer (Burnett), in his article in the last number of the *Archives f. Oph.*, *viz.:* that the cause of some cases of color-blindness is to be found in the brain-centre and not in the retina; and thinks that the defect in color-sense can be improved by exercise. He thinks Holmgren's test tends to magnify slight defects in the color-sense, and that more than one method of examination should be used where we want extreme accuracy.

C. S. Bull. A contribution to *the Pathology of Orbital Tumors;* being a study of the secondary processes in the peri-periosteum and bones of the orbit and vicinity (N. Y. *Med. Journal*, March).

Case 1.—Encapsulated orbital sarcoma; extirpation; return of the growth as a myxo-sarcoma; infiltration of the bones of the orbit, and of the facial bones of the left side in general; three operations for the removal of the tumor.

Case 2.—Intra-ocular sarcoma; secondary infiltration of the optic nerve and orbit; degeneration of the orbit and face; four operations for the removal of the growth.

Case 3.—Fibro-sarcoma of the orbit, involving the periosteal lining, and subsequently, the bones of the orbit and face.

B. concludes, from a study of these cases, that such growths are not fit subjects for operative interference." We would most emphatically endorse B.'s opinion, as experience, in numerous cases similar to his, has taught us how futile operative interference has proven itself to be.

J. C. Dalton. *Centres of Vision in the Cerebral Hemispheres* (N.Y. *Medical Record*, March 26th). From experiments performed on dogs, D. feels justified in concluding: "1. Extirpation of the angular convolution causes loss of visual perception on the opposite side. 2. This operation is not followed by any disturbance of the intelligence, attitude, power of locomotion, or general sensibility. 3. It does not interfere with the local sensibility of the retina or conjunctiva, the reaction of the pupil to light, nor with the normal consentaneous movements of winking. Its effects are, therefore, confined to the exercise of visual sensibility.

I. P. Wall. *Congenital Absence of the Eyeballs* "Anophthalmia" (N. Y. *Med. Record*, Mar. 26th). The tutamina oculi were perfectly formed, but there were no eyeballs, even in a rudimentary form. The lachrymal gland was present. The child was a white male, and six months old.

W. C. Ayres. *The Physiology of the Visual Purple* (N. Y. *Med. Journal*, May). A. sums up his conclusions as follows: "We know that the purple is a photo-chemical substance which is sensible to light, and that its seat is in the outer segments of the rods, whereas it is never found in the cones. The cones, on the other hand, being the only elements found in the fovea centralis, we are forced to the conclusion that distinct vision, both for objects and for colors, is independent of its existence. In the higher classes of animals it is sensitive to light, but in some deep-sea fishes, cephalopods, etc., it has its seat in the rods, but is no longer sensitive to light, although it has the same color as before. Where it is not sensitive to light the optical structure of the eye is very defective. It is an albuminoid compound, and is a secretion of the pigment epithelial cells of the retina; but this secretion is not controlled by any of the larger nerve trunks, which have a part to play in the functions of the eye. We know of no drug which can diminish its secretion, but pilocarpine and muscarine greatly increase it."

In their report on the Progress of Ophthalmology, for the first half of the year 1880,* Drs. H. Magnus and A. Nieden, note the following:—

Beauregard. *Suppuration of the Vitreous.* B. says the pus cells come from the cells of the choroid. (Sec. *de Biol*, Paris, June 12th, 1880.)

Knies, M. *Argyria Oculi* (Z. M., Vol. xviii, p. 165). After external application of the nitrate of silver stick for fifty years, K. observed two modes of staining of the tissues, one being diffused, the other consisting of minute granules. The cornea was stained brown, especially in the centre; the epithelium and endothelium of Descemet's membrane were free; the subconjunctival tissue was, in its whole extent, pervaded by lymph spaces, which were densely filled with granules of silver. In transverse sections the blood vessels were surrounded by black rings, the adventitia being densely filled with granules.

Haltenhoff. *Conjunctival Hemorrhage* in a new-born child. Hæmophilia; uncontrollable hemorrhage caused *death* in thirty-six hours (Rapp. sur. les trav. dela. Soc. Méd. de Genève, p. l'an, 1879).

Högyes, A. *The Changes of the Eye after Extirpation of the Facial Nerve* (*Archiv. f. Exper. Pathol.*, Vol. xi, p. 258). After simple division of the nerve permanent affections of the cornea are rare; after evulsion, the cornea becomes dry, with more or less extensive ulcera-

* Translated by R. O. Born, M.D., of N. Y., *Archiv. Ophthal.*, Vol. x, No. 2.

tion; after division of the trigeminus the eye is always lost by the subsequent neuropathic keratitis.

KRETSCHMER. *Keratitis Neuro-paralytica.* Panophthalmitis after neurectomy of the infra-orbital nerve (*C. f. A.*, March, p. 65, with polemic correspondence, l. c., pp. 163, 236, 293, 363).

GALEZOWSKY. *A Case of Congenital Irideremia* (absence of the iris) through several generations (*Rec. d' Oph.*, 3, No. 2, Feb).

WOLF (Glasgow). *A Case of Bleeding Tumor of the Iris*, about four mm. in diameter, bleeding every four to six weeks (*Med. Times and Gaz.*, May 8th, p. 504).

CHISHOLM, J. J. *A piece of metal in the eye for 23 years, without causing sympathetic ophthalmia* (*Bost. Med. Jour.*, Vol. CII, p. 248).

SCHNABEL. *Secondary Glaucoma.* Upon an observation of glaucoma after traumatic luxation of the lens and stretching of the fibres of the zonula in incarceration of the capsule into the wound, the author is opposed to Knies' view of an occlusion of Fontana's spaces. The abnormal stretching of the zonula is said to be the only cause of glaucoma, especially since the author observed the cure of an acute attack in chronic glaucoma, by the spontaneous luxation of the lens, with detachment, and thus relaxation of the zonula (*Wien. Med. Bl.*, Vol. III, Nos. 6 and 7, p. 130).

BREMER, VICTOR. Among 223 *deaf-mutes*, HANSEN and KRENSCHEL found 9 cases = 4 per cent. of *retinitis pigmentosa* (*Inaug-Dissert., Kopenhagen*, 1880).

GATLI, FR. *Amaurosis produced by salicylate of soda poisoning* (*Gaz. Degli. Ospit.*, Vol I, p. 129).

URTHOFF. *Atrophy of the optic nerve*, with special consideration of, 1, the causes; 2, the knee phenomenon (patellar-tendon); 3, the condition of the visual field. It comprises 83 cases. The knee-phenomenon is absent in 13 out of 15 cases of spinal atrophy of the optic nerve, in one-third of the cases of genuine progressive atrophy, and is, therefore, a valuable symptom for the differential diagnosis. In 7 patients there was at the same time myosis. In spinal and simple optic nerve atrophy, the limitation of the visual field begins in a small majority of cases at the outer side (*A. f. O.*, Vol. XXVI, No. 1, p. 244).

HAFFNER. *Rare migration of a round worm*, 3 cm. in length, *into the left lower lachrymal canal*, in a child suffering from severe whooping-cough (*Berlin. Klin. Wochensch.*, No. 24).

SIGSMUND. A small *splinter of wood* kept *in the eye for 47 years without any disturbance* (*Berlin. Klin. Wochensch.*, No. 5, 1880).

ERB. *The ocular affections in tabes dorsalis.* Among 56 cases there was seven times atrophy of the optic nerve, and seventeen times paralysis of ocular muscles (*Deutsch. Archiv. f. Klin. Med.* 1879).

STEWART, GRAINGER. The *eye symptoms in locomotor ataxia.* Among 70 cases there were 20 cases of squint, three of ptosis, four of diplopia, without manifest squint; seven of myosis, four of difference in the pupillary diameter, eight of immobility to light, while the pupils contracted upon convergence; four times temporary amblyopia with subsequent improvement; fourteen times atrophy of the optic nerves with amaurosis in one-half of the cases at quite an early period (*C. f. Med. W.*, 1880, *p.* 62).

HOSCH (Basel). *Embolic Panophthalmitis* in *Puerperal Fever.* Literature of 15 cases. H. found in one case large accumulations of micrococci in some of the smaller retinal vessels, also in numerous uriniferous tubes, and in more developed stages in the vitreous body (*A. f. O.*, Vol. xxvi, No. 1, p. 177).

News and Miscellany.

COMMENCEMENTS.

University of Pennsylvania.

The Annual Commencement of the Medical and Dental Departments of the University of Pennsylvania came off at the Academy of Music on Wednesday, March 15th. At a few minutes before twelve o'clock, the trustees, faculty, alumni, and graduating classes entered upon the stage, and after "music," prayer was delivered by Rev. William H. Furness, D.D. Provost Pepper then conferred the degree of Doctor of Medicine on 122 graduates.

The degree of Doctor of Dental Surgery was then conferred on 41 graduates of the Dental Department.

Of the four prizes offered for the competition of the members of the graduating class, two were taken by Drs. Howard A. Kelly and Horace L. Jayne, conjointly. The Anomaly Prize, instituted by the late Dr. H. Lenox Hodge, and continued by Dr. Charles T. Hunter (present Demonstrator of Anatomy), was given to Doctors Kelly and Jayne, for a record of over 1200 anomalies.

The preparation prize, offered for the best preparation of some portion of the human organism, was awarded to the same gentlemen.

The "Henry C. Lea" prize to Drs. T. D. Gootald and Horace L. Jayne. Alumni Prize to Drs. G. T. Robinson and H. Will. Distinguished Merit. Drs. G. W. Johnston, C. H. Reed, H.

E. Smith, A. J. Daland, A. D. Smith, G. E. Shoemaker, C. Claxton, W. F. Hænhlen, and D. A. Randolph.

Honorable Mention—George M. Boyd, C. S. Dolley, J. L. Elliott, W. M. Gray, H. A. Kelly, C. R. Matchett, D. W. B. Rupp, C. H. Loder, McC. Radcliffe, J. Schmidt, P. N. K. Schwenk, D. W. Shelly, John E. Sheppard, J. S. Tait, W. J. Taylor.

Morgan Anatomy Prize—J. W. Blackburn, with honorable mention of William H. Steward.

Osteological Prize—E. C. Fahrney, with honorable mention of M. Howard Fussell.

In the Dental Department the following graduates received honorable mention—James H. Abrams, John A. Fothergill, Charles M. Stetson, Gabriel Oltramare, Martin H. Meisser, John G. Sharpe, Edward H. Allen, and William McNair.

In the opinion of the oldest teachers, this class was, physically, the best looking; mentally, the most vigorous; in manners, the most favorable; and professionally, the most satisfactory ever sent out from the University. Fifty-one reached averages over ninety, an attainment which has so impressed the faculty with the advantage of the higher requirements introduced, and the power of the best class of students to meet them, that next year the average will be raised to ninety-five. Out of an original class of 159, only 122 graduated, 37 being unable to meet the requirements. This year's class sent out on the invitations "*no flowers.*"

The valedictory was delivered by James Tyson, M.D., Professor of General Pathology and Morbid Anatomy. In beginning, Dr. Tyson alluded to the first annual commencement at which medical degrees were conferred in America. That occasion, he said, was the commencement, held June 21st, 1768, of the College of Philadelphia, of which the University of Pennsylvania is the direct lineal descendant and successor.

Under the old system, developed since then, a student, if he desired, could earn his degree of doctor of medicine in two courses of medical lectures of but five months' duration. All other trades and occupations required three, and even more, years—not of verbal instruction, but of actual hand labor—before the learner was considered fit to carry on his business independently of his master or teacher. This was the case with the carpenter, the stone-cutter and machinist, but the physician, who dealt with human life and its tenement, was often qualified by eighteen months' instruction, and even less.

Of the results of what is termed the "new plan," introduced in 1877, he spoke most favorably, and cited as one of the results that twenty-eight per cent. of the whole number of full course students attending the past session are college graduates. The faculty, therefore, he says, is encouraged and already committed to making the winter term of instruction hereafter six months, instead of five. "Nor will they be satisfied," says Dr. Tyson, "until an academic year is obtained of the same length as that of the collegiate department—that is, nine months—and the finished physician shall not only be thoroughly trained in all that pertains to his profession, but he shall also possess a university education, or its equivalent."

The class organization of this year's graduates was as follows: Charles R. Matchett, President; Timothy L. Barber, Vice President; George H. Wattles, Secretary; Peter M. K. Schwenk, Treasurer; Charles Claxton, Historian, together with an executive committee.

The Annual Faculty Supper was given to the graduating class on commencement night, in the new college building.

Woman's Medical College.

The Woman's Medical College of Philadelphia held its Annual Commencement at Association Hall, on Thursday, March 16th. After music and prayer by Rev. Charles G. Ames, the graduates were addressed by J. B. Walker, M.D. Professor of Practice of Medicine. He said:—

"Many of the graduates have been provided for by engagements to serve as resident physicians in large hospitals, where they will have opportunity to acquire an aptitude in the practical application of the knowledge in store. There are very few hospitals, however, which are open to women as resident physicians, and the Doctor said he was pleased to know that most of the fair graduates have mapped out an independent career, which will enable them, for a few months at least, to take up a course of study at the public clinics, which are now open to women.

"The fact is growing into popular acceptance," he said, "and admits of no refutation, that a profession which can grace man with dignity and highest honor cannot possibly be distorted into conferring disgrace and dishonor upon woman. Yet there are those who would have us believe you have soiled your hands and deformed your minds, as well as polluted your hearts, in espousing the study of medicine. Impossible. There is nothing connected with scientific inquiry which can tarnish purity or soil clean hands. It does not transform, it develops; and she who is graced with true womanliness will find it grow with the growth of her entire psychical nature under this, as under any other process of true culture."

The degree was then conferred upon nineteen graduates.

Medico-Chirurgical College.

The first annual commencement of the Medico-Chirurgical College was held at Association Hall on March 14th, and was largely attended. The exercises were begun by prayer by the Rev. George H. Johnston. Degrees were conferred by the President of the Trustees and Faculty, George P. Oliver, M.D., upon the following graduates: Parmenas Appleman, of Ohio; Thomas H. Hicks, of Canada, and Leolf Reese, of Pennsylvania. The valedictory address was delivered by Professor William F. Waugh, M.D., and a statement of the object and work of the college was read. Thirty students have now matriculated.

Starling Medical College.

The Starling Medical College, of Columbus, Ohio, at its last commencement, held February 23d, conferred diplomas upon fifty-two graduates, the largest and best class in many years.

Central College of Physicians and Surgeons of Indianapolis.

The third annual commencement of this College was held February 28th. There were eight graduates.

The Waters gold medal, for best thesis on chest diseases, a case of surgical instruments, and the valedictory honors, were all conferred on S. E. Sharp, B.S. The exercises were short, timely and interesting.

Alumni Society Meeting.

The Alumni Society of the University of Pennsylvania held its annual meeting, in Medical Hall, on the evening of March 14th, Dr. John H. Packard presiding.

Dr. James H. Hutchinson, Chairman of the Executive Committee, made this announcement: "The importance of having a literary journal under the direction of the University impressed itself upon the General Association of University Alumni, and resulted in negotiations being made and effected by which the *Penn Monthly* magazine came into the control of University men."

It was stated that the foundations of the new addition to the University Hospital, as the gift of Mr. Henry C. Gibson, were now being laid.

The following officers were elected for the ensuing year:—

President—Dr. John L. Atlee.

Vice-Presidents—Drs. Alfred Stillé, Meredith Clymer, W. S. W. Ruschenberger, Thomas J. Gallagher.

Treasurer—Dr. Thomas Holmes Cathcart.

Corresponding Secretary—Dr. H. R. Wharton.

Recording Secretary—Dr. Horace Y. Evans.

Executive Committee—Drs. Hiram Corson, Andrew Nebinger, John H. Packard, James H. Hutchinson, John Ashhurst, Jr., William F. Norris, Samuel Ashhurst, Thomas J. Yarrow, R. A. Cleeman, James Tyson, William Pepper, S. S. Stryker, Wharton Sinkler, Charles T. Hunter, C. B. Nancrede, Louis Starr, C. M. Seltzer, B. Alexander Randall, Edward S. McIlvaine, Charles R. Matchett.

Orator—Dr. Hiram Corson, of Pennsylvania.

Report of Fulton Co., N. Y., Medical Society.

The annual meeting of the Society was held at Gloversville, January 12th, 1882.

The retiring President, Dr. D. S. Orton, read an interesting paper on "Thrombosis." An essay on the subject of "Vaccination" was read by one of the members, in which the ground was taken that vaccination is and has been productive of more harm than benefit. The views of the writer were thoroughly disapproved by the Society; and its expression was in favor of vaccination and of re-vaccination every few years.

The officers elected for the ensuing year were, Dr. P. R. Furbeck, President; Dr. A. Z. Avery, Vice-President; Dr. I. de Zouche, Secretary; Dr. D. V. Still, Treasurer, and Dr. C. M. Lefler, Delegate to State Medical Society.

International Medical Congress.

It has been decided that the next International Medical Congress will be held in Copenhagen, in 1884.

A Tribute to Dr. Pancoast's Memory.

The Alumni Association of the Jefferson Medical College met March 9th, to take action upon the recent death of Professor Joseph Pancoast, M.D. Professor Gross, who presided, spoke feelingly of his relations with the deceased, whom he had known for fifty-four years, and reviewed the important medical and surgical works of Dr. Pancoast. Drs. A. Hewson and John H. Brinton also spoke, and Dr. Richard J. Dunglison offered appropriate resolutions of regret, which were adopted by the Association.

Attempted Assassination of Dr. Gray.

Dr. John P. Gray, Superintendent of the State Lunatic Asylum at Utica, New York, who was one of the principal expert witnesses in the Guiteau trial, against the insanity plea, was shot in his own private office, on the evening of March 16th, by a lunatic. The ball passed through both cheeks, but the wound is not considered fatal. The would-be murderer (who voluntarily gave himself up), Guiteau like, claimed a divine mission of eighteen months' standing, to kill Dr. Gray.

Smallpox in Bethlehem.

This disease has assumed epidemic form in Bethlehem. The health commission do not know of a single case in which a person previously successfully vaccinated has taken the smallpox. All precautions have been taken to prevent the spread of the disease.

Dr. Lamson.

Dr. Lamson, to whom we referred some time since as under arrest in London, on the charge of fatally poisoning his brother-in-law with aconitia, having been found guilty, his friends are trying to have him proved insane, from the excessive use of morphia.

——On p. 288, column 1, line 33, for *pause* read *panse.*

MARRIAGES.

BRUEN—WHELEN.—In Philadelphia, February 21st, Edward T Bruen, M.D., and Sarah Y., daughter of the late Townsend Whelen.

EDWARDS—COLLINS.—At New Haven, Conn., Tuesday, February 28th, 1882, by Rev. Noah Porter, President of Yale College, Dr. Jonathan Edwards, formerly of Troy, N. Y., and Marion, youngest daughter of the late David C. Collins.

DEATHS.

GILLAM.—In Windsor, N. C., on Friday, February 24th, 1882, Francis Gillam, M.D., in the 42d year of his age.

PARKHURST.—At Englewood, N. J., on Wednesday, March 1st, Dr. Chester Parkhurst, in the 79th year of his age.

PETTINGILL.—Lucius L. Pettingill, the only surviving son of Samuel C. Pettingill, M.D., died at Hancock, Delaware Co. New York, on Wednesday evening, February 8th, 1882, in the 40th year of his age.

VAN SLYCK.—In Brookline, Mass., February 18th, 1882, Frances Dorcas, eldest daughter of Dr. D. B. and Annie E. Van Slyck, aged 19 years, 6 months and 20 days. Interment at Oswego, N. Y.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

SYMPTOMS AND TREATMENT OF DIPHTHERITIC PARALYSIS.

Delivered at the Hôpital des Enfants Malades,

BY M. ARCHAMBAULT,

Physician to the Hospital.

Translated for the Medical and Surgical Reporter.

Gentlemen:—We have at present in the St. Louis ward a young boy, 14 years of age, with diphtheritic paralysis, who presents most of the symptoms usually observed in the disease, and will enable me to give you a brief, yet sufficiently complete, account of this interesting affection.

This boy was admitted to the hospital on October 12th, almost at the same time with his brother and two sisters, all stricken down by diphtheria. He was discharged convalescent on November 2d, but one of his sisters succumbed. It was one of those localized epidemics where direct contagion is the principal factor in the propagation of the disease, and several members of one family are taken down almost at the same time. As for this young lad, the disease in his case was of moderate intensity, the glandular enlargement was not marked, there was no trace of albumen in the urine at any period of the malady, and he was able to leave the hospital after twenty days' sojourn.

For twenty days afterward he remained apparently well, but toward the twenty-second day his voice took on a nasal character, resembling that observed in cases where there exists perforation or division of the velum palati; a little later he had some difficulty in swallowing, particularly liquids, which returned by the nose; then, after a few days, he complained of pain about the middle of the forearm, and finally the upper limbs, particularly the left, became more and more feeble, he was awkward in using them, and was apt to let fall anything held in the hand.

Eight days since he observed that he tripped easily in walking, and that the lower limbs became feeble, particularly the left, just like the upper limbs.

Here the motor troubles do not appear to have been preceded by any alteration of tactile sensibility; the patient says that at first he had double vision, but of this there is now no trace.

At present, as you have observed in the ward, the paralysis has extended to the muscles of the thorax, for the boy can no longer sustain the weight of the head, and lifts himself in bed with great difficulty.

I will, however, examine the patient in your presence, so that you will be better able to follow the enumeration of symptoms and make the study of the case, as it were, *de visée*. You remark the nasal intonation of the voice and the difficult and indistinct articulation. He cannot blow out the cheeks by holding air in the mouth, on account of the imperfect contraction of the orbicularis oris, and also on account of the paralysis of the velum palati, which permits the air to escape by the nares. He can hardly extinguish a candle, because in the effort a considerable portion of the air escapes through the nose. The boy can no longer whistle, partly on account of the paralysis of the orbicularis oris, but especially because the floating velum palati can no longer completely obstruct the posterior opening of the nasal passage; what proves this, is the fact that

if the nose is compressed between the fingers, the boy can whistle longer, but not perfectly.

If he attempts to take a draught of water a part returns through the nose; another proof that at the moment when contraction is produced by deglutition, the velum palati is incapable of closing completely the posterior orifice of the nares, whence the reflux of liquids.

At this moment, also, a part of the same liquid should enter the larynx and induce cough, but such is not the case, and the patient informs us that this rarely happens; whence we may conclude that the occlusion of the larynx is sufficiently complete, which is not often the case in this malady, for ordinarily, each attempt at deglutition of liquids induces repeated and painful attacks of cough. The patient does not sneeze when the mucous membrane lining the nares is irritated, nor does he seem to feel the passage of liquids, an indirect proof that there is anæsthesia of these mucous surfaces. He is totally unable to gargle, for as soon as any liquid arrives in the pharynx it is either immediately swallowed or rejected through the nose, as the muscles of this region do not contract firmly and harmoniously enough to retain the liquid and agitate it in the throat, as is necessary when a gargle is used.

From this ensemble of symptoms we may conclude that there is paralysis of sensibility as well as motility; this can be seen by direct inspection, when it will be seen that the soft palate is fallen, and is but little contracted, when the patient attempts to emit the sounds ah and oh. It can also be touched with a feather, without inducing contraction, and this experiment does not produce, by reflex action, any efforts at vomiting, which would infallibly ensue if the velum palati and the surrounding mucous membrane were in the normal condition.

If, however, the feather is pushed as far as the pharynx, efforts at vomiting ensue, showing that the contact of the foreign body is felt and transmitted to the nervous centres. There exists, then, in this child, almost complete paralysis of the velum palati, affecting its sensibility and contractility; paralysis of the same nature but less advanced, of the pharynx; incomplete paralysis or notable feebleness of the orbicularis oris and buccinator.

The tongue is agitated as in general paralysis. You will notice also that there seems to be no expression to the face, that the boy has almost the aspect of an idiot, although he is very intelligent. He can smile but imperfectly; the facies is that of a statue; this condition I can only explain by the supposition that there exists paralysis, or rather, paresis of the entire muscular apparatus of the face.

If we now proceed to the examination of the limbs and thorax here is what we find:—

There is marked analgesia of the forearm, which diminishes as we mount toward the root of the limb. The patient feels the contact of different objects, and determines their temperature better over certain points. We find, then, in general, that there is diminution of tactile sensibility more marked over the parts where the patient first complained of pain. For the lower limbs the sensory troubles appear, as in the upper, more marked toward the extremities, but irregularly distributed; that is, tactile sensibility is completely gone at one point while it is normal just beside it.

The pressure of the hand is very feeble, particularly with the left, and he can lift nothing of any weight. It is probable that the dynamometer would show a notable diminution in the force of muscular contractility, as has been shown by Trousseau. But what is not less remarkable is the default in precision of muscular contractions; the hands are shaking and agitated, as in general paralysis, and the patient can hardly take up any small object. He can take with ease a tumbler, but he has great difficulty in controlling the motions of the fingers and bringing them together with sufficient precision to pick up a pin from the table. There exists, then, very marked paresis, and, as it appears to me, a certain degree of incoördination of movement.

For the inferior limbs the motor troubles are yet more marked, or, at least, more evident. The patient can sustain himself on his limbs if he has something to lean on, but if he attempts to walk, he trembles and stumbles, and would certainly fall if not held up. The left leg drags, and is manifestly feebler than the right, so that though this state of paresis seems almost generalized, there yet exists a certain degree of hemiplegia, which would lead us to admit that if there is, as I believe, any material lesion of the nerve centres, it would predominate on the right side if cerebral, on the left side if below the crossing of the pyramids.

There is some incoördination of movement, the patient throwing his limbs about, as in ataxia; he does not well feel the ground under his feet, and walks better when he can follow the motions of the limbs with his eyes. It is certain that the diminution of sensibility and the enfeebled sense of muscular contraction are very important factors in producing these paralytic manifesta-

tions, for when the patient is lying down considerable effort is necessary to flex the limb or to extend it when flexed.

This incomplete paralysis is generalized; all the muscles of the thorax, even, seem affected; it is with difficulty that the boy lifts his head from the pillow, and it is only after great efforts, and rolling from right to left, that he can manage to place himself in a sitting posture in the bed.

The muscles of organic life do not appear to be affected; the patient has been extremely constipated, and there may, perhaps, exist some degree of paralytic inertia of the intestines. The upper eyelids are somewhat fallen, but as there exists granular conjunctivitis, this may explain the incomplete blepharoptosis. The pupil is not dilated, and ophthalmoscopic examination reveals no alteration of the interior of the eye.

There is no trace of albumen in the urine, and there never has been, even during the course of the primary malady.

The symptoms observed in this case are sufficiently typical to give you a complete idea of the malady, and we will now be able to consider the proper course of treatment.

Treatment.—Attention must first be paid to the general health, for such patients are usually in a state of profound anæmia when convalescent from a more or less intense attack of diphtheria, as you must have often remarked in the wards of this hospital. They are pale and feeble, and you will generally find a blowing murmur in the cervical vessels. And this anæmic condition is generally more marked in cases where paralysis follows diphtheria, so that I am in the habit of giving the muriated tincture of iron to such patients, in doses of from five to fifteen drops. In conjunction with iron, I have found the arsenical preparations of great advantage. The preparation most frequently employed in this hospital is the liquor potassii arsenitis, or Fowler's solution, of which the dose may be carried, without difficulty and gradually, to ten or twelve drops per diem, for a child of from five to eight years of age. The two medicaments may be given conjointly at meal times, in a little wine.

As you can well understand, the syrup of the iodide of iron and the ferruginous elixir of M. Rabuteau also answer all the indications for treatment. I also administer during the day, by dessertspoonfuls, a brandy mixture containing thirty grains of extract of quinquina (Fr. codex), and eight or ten minims of tincture of nux vomica. If the tincture induces vomiting, it may be necessary to omit it, or it may be advantageously replaced by some preparation containing sulphate of strychnia, such as the syrup of the French codex, which contains $\frac{1}{120}$ of a grain in one teaspoonful, and is easily taken and well supported by the stomach. At the same time the more generous wines may be allowed.

When the paralysis is generalized, I make use of the continuous electric current, placing the positive pole over the cervical region and the negative at the lower part of the vertebral column, or on one of the limbs.

M. Trouvé has constructed small electric machines of six elements, which are not above the means of most families, and nothing is more simple than to instruct some one about the patient in the use of this little apparatus.

These continuous currents may be maintained for hours if but four elements are used; when six are employed the machine should not be left so long in action. It has seemed to me that in cases where the paralysis was very marked this means of treatment proved of great utility.

When I consider that the diaphragm is enfeebled, I make use of electricity, so that the current will traverse that muscle; and in the same way when there is paralysis of the intrinsic muscles of the larynx. In order to act on the nerve extremities, and, consequently, on the paralysis, dry friction or massage should be made over the entire body, with the hand simply covered with a glove or with a soft woolen brush; frictions with a horse-hair glove are much too rude. The woolen glove used for the frictions may often, with advantage, be first wetted in some alcoholic solution; in such case the massage produces a sensation of cold, which is soon followed by general reaction, which much invigorates the patient.

Or a large flannel gown may be made so as to fasten about the child's neck, and he may then be subjected to a species of vapor bath, gum benzoin or juniper berries being burned on a small brazier placed so that the fumes mount under the gown; while this is going on the little patient can be vigorously rubbed through the flannel. This cannot be done at the hospital, and we are obliged to content ourselves with salt water and other baths. When recovery is slow and the season permits, nothing is more apt to hasten it than a sojourn at the seaside, with sea bathing.

When paralysis of the pharynx induces pronounced dysphagia, it should receive most careful attention from the physician, particularly if tracheotomy has been performed and the wound in the throat is still open. Remembering that compact substances are most easily swallowed,

thick soups and macaroni cooked in milk may be given, and drinks may be administered slowly with a spoon. If the wound in the trachea is still open, it will be necessary to occlude the orifice while the child drinks, for deglutition is easier where this is done. But the children are often completely spent by fruitless endeavors to satisfy their thirst, and also fatigued by the constant fits of coughing at each attempt to swallow, so that they finally refuse all species of liquid, and there is great difficulty to introduce sufficient food to keep them alive. In such cases very thick soups may be given, which are at the same time an aliment and a drink. These may be thickened with the different lichens, Irish moss, etc., or with gelatine.

When the patient can swallow nothing, it becomes necessary to introduce food by means of the œsophageal tube, which is not always easy to pass in children. The soft rubber œsophageal tube, such as is made at present, should be used so as to avoid all chances of injuring the soft parts. Concurrently with these means of sustaining the system, analeptic enemata, particularly those compounded with the different peptones, are of very great benefit. Such an enema may be made up as follows:—

℞. Salep, gr. xxx
Thin beef soup, without salt, ℥ ivss
Yolk of egg, No. j or ij. M.

By means of an electric current passing by the larynx, deglutition has been facilitated, and the contractility of the intrinsic muscles of the larynx awakened. The paralysis of the diaphragm should be combated with perseverance, by means of the electric current, and this paralysis should receive special attention, as it is one of the direct causes of death.

Strabismus and blepharoptosis should also be treated by electricity, but here there is less urgency, as these are of little importance, and always finally disappear. The visual troubles induced by the default in accommodation are corrected by a collyrium containing eserine:—

℞. Sulphate of eserine, gr. v
Aquæ destil., f℥ j. M.

A few drops in the eye, morning and evening.

Here again there is little need of therapeutic intervention, for the visual troubles are always fugacious and disappear completely after a certain length of time.

—The Paris Académie des Sciences has awarded the Grand Prix Lecaze, of the value of $2000, to Professor Brown-Sequard, as a reward for a lifetime devoted to physiological research.

Communications.

THE EPIDEMIC OF RÖTHELN IN SUMTER CO., ALABAMA, IN 1880.

BY EDWARD H. SHOLL, M.D.,
Of Gainesville, Ala.

From the Alabama State Medical Transactions of 1881.

Having found it impracticable, after careful inquiry, to definitely fix any facts in reference to the time and place when this disease first made its appearance in Sumter county, it may be well to state in the outset that the portrayal of the disease herewith given is drawn from personal observation and tangible practical experience.

The first case seen was in April, 1880, the last one three days since, February 15th, 1881. Through all those ten months there has been more or less of it, quiescent sometimes for two months, then breaking out afresh some miles away, without any direct contact, that could be ascertained, with the previous case.

Definition.—An eruptive disease of specific character, distinct, separate, of its own kind, and contagious, ushered in by three to four days of discomfort from excess of tears, inflamed eyes, and irritation of nostrils and throat, and greater or less heat of skin.

On the third or fourth day the eruption appears, pinkish, pointed, projecting at first, but in a few hours deepening in its reddish color, and passing from the point to the crescent, and then to irregular shaped and slightly elevated patches of a size varying, according to the severity of the disease, from half to one and a half inches in diameter, lasting from three to ten days, transmissible from the pregnant mother of seven months to her unborn child, and developed in a few days, as I have seen it, after the birth of the child. It is followed by desquamation, which sometimes protracts itself for forty to fifty days.

Pathology.—It is right and in accordance with diseased conditions of the system, that this disease, as specific and distinct in its being and kind, should be remanded to its proper place, and hold it as an entity, a unity in cause, course, result, of its kind, and its own kind, no hybrid, and I would here assign it to its true place in the records of disease, as one and only one in all its various grades, times, places and surroundings.

This I do with all deference to the German, English and Scotch authorities who have written on the subject, for close observation and experience have taught me that time, place and circumstance may modify or give a peculiar livery to a disease, but never blend it into oneness with

another, by which it shall merge its own type, and assume the distinct elements and potentialities of a new disease, as the child, who may intermingle the pronounced features and individualities of its two parents.

In the Cincinnati *Medical News*, of April, 1876, Dr. A. J. Miles gives four reasons for assigning it a place as a distinct disease. The claim that I shall lay for its individuality is based upon a study of the disease in my own person, lasting, from its inception, in May, to the last distinct evidence of peeling, for sixty days, during all which time I watched its varying manifestations with a precision that cannot possibly be accorded to the observer of any disease in another person, for the sense of constant companionship with and service to the disease ceases only during the hours of sleep.

Symptoms.—First, a sense of languor and general discomfort, with depression of spirits, followed in a few hours by shiverings, with slight reduction of heat of skin, which in a few hours rises above the normal standard, attended by red and watery eyes, sneezing, frontal pain, sore throat, constriction of chest, nausea, pain in the back and limbs, with increased frequency of the pulse, and drowsiness, incident to a want of proper decarbonization of the blood, this attributable in its turn to the blood poison and the want of proper aeration of the blood in the lungs already embarrassed by the bronchial trouble.

In my own and all the cases noted, mild or severe in type, the sore throat was the most prominent and distressing symptom. In from seventy-two to ninety-six hours from the first invasion, the eruption, in deep pinkish and distinct points, makes its appearance, first on the face, neck and arms alone, in others gradually covering the whole body, deepening in shade and coalescing in bulk, until it passes in color from a pinkish to a crimson and almost coppery shade, and in form to irregular shaped and elevated patches. These, in every case noticed, followed the order of single points, or a number of points gradually commingling into a concentric shape, as in measles, and lastly into masses of irregular conformity and size.

In my own and other cases of moderate severity, the duration of the eruption, well-marked and defined, was ten days, from which time it gradually disappeared, but could be seen at any time for twenty days thereafter, when the body was relaxed by vigorous exercise on a hot day. During the first four days of the eruption the symptoms are all aggravated, and the amount of discomfort and suffering is vastly beyond what the frequency of the pulse or heat of skin would seem to indicate. The headache is now more pronounced, pain sharp, darting, and most severe above the eyes, rendering it at times, apart from the weak and irritated eyes, almost impossible to hold the eyes open. There is intolerance of light, lids are tumid, lachrymation is increased. The sense of constriction of the chest grows apace, and is annoying, requiring occasional deep inspirations for relief, sometimes accompanied with severe paroxysms of coughing, which, at first dry and husky, are gradually relieved by a moderately free expectoration of frothy mucus. Nausea is a common symptom. Seldom, however, do we have vomiting, except in the effort to clear the throat of the tenacious secretion.

Of all the symptoms, the sore throat is the most constantly present, and is distressing even in some of the mildest cases. It presents a swollen appearance. It varies in color, from a fiery and deep crimson to a livid purple, is intensely congested, with tonsils much enlarged. The effort at swallowing now becomes difficult. A constant secretion of tenacious and tough mucus requires a like almost constant effort to dislodge it, and compels the sufferer to maintain the erect or prone position. Sometimes there is a considerable external swelling. The voice becomes hoarse, husky, and is almost lost. Talking becomes painful, and in the attempt to swallow, which at times is well nigh impossible, there is a forcing back of fluid through the nose, and impending suffocation seems to threaten. In a class of cases more aggravated than I have seen, the increase of a vitiated mucus goes on, the cough becomes constant, the powers of life give way, and the patient dies by suffocation, convulsions, or coma.

No one who has not suffered with the sore throat of this disease can form any suitable idea of its distressingly annoying and painful character, allied as it is with the teasing cough. Wearied with constant effort, unable and afraid to sleep, for fear of suffocation, the sick man turns and tosses, wishes in the morning for night, in the night for morning, and if he steals a moment of rest, wakes from dreams of horror to a reality of misery.

From the fourth to the fifth day after the appearance of the eruption, the symptoms, in case of returning convalescence, begin to decline, and at the expiration of ten days a sense of discomfort and debility alone is left.

I have given the type of a case of ordinary severity. It shades off into light or darkness,

as the attack is less or more severe Some symptoms are absent in mild cases, but the sore throat is present in them all. In my own case no eruption could be found at any stage, save on the face, neck and hands. The temperature range is from 99.3° to 103°. The first was uniform with me for three days of the eruption. The pulse was from 84 to 120. The tongue is ordinarily but slightly coated, is red on tip and edges, with a constant craving for acid drinks, which desire was freely satisfied with lemonade and buttermilk.

The decline of the disease was accompanied with a profuse watery diarrhœa, of a pale yellow color, discharges in thirty-six hours relieving the throat, cough and itching of the skin.

About the twelfth day from the appearance of the eruption, desquamation began and continued for forty-eight days, at the end of which time the last peeling from the hands took place. From the throat and on portions of the face the shedding was by branny scales and rolls. From the hands the process went on slowly by a literal peeling, the inner part of the hand, wherever commonly subjected to pressure, turning a deep saffron yellow prior to the shedding. On the sole of the foot the peeling was confined to the toes; the rest of the foot shed itself in scales.

During the whole period of desquamation I was never well, and though attending to my ordinary duties, did it carrying weight, mind and body alike sluggish, appetite and digestion indifferent, with frequent headaches, and more than ordinarily copious secretion of limpid urine, which, in the morning particularly, scalded the urethra in its passage, and had at times a distinctly ammoniacal odor.

Fortunately, I cannot give any of the anatomical lesions from practical observation. They will be inferred from the nature of the disease, and will be found in the throat, lungs and kidneys.

Diagnosis.—In the initial stage it may be readily separated from scarlet fever by the duration of the premonitory symptoms prior to the appearance of the eruption, as in scarlet fever it is, in the great majority of cases, but twenty-four hours after the premonitory chill before the eruption appears. In this disease it is not seen until the third and fourth days. From measles, it is best distinguished by the almost constant and inevitable attendance of sore throat from the beginning. The eruption appears at first in small points, pinkish, lacking the deep red of scarlet fever, and less diffuse, coalescing afterwards in various sized and somewhat elevated patches, becoming a dark red, which, in fading out, assumes sometimes almost a coppery appearance, and generally not as completely diffused in its character as measles. The duration of the eruption in rötheln, in a case of any severity, is longer than in scarlet fever or measles.

The constant accompaniment of a sore throat, severe in its character beyond other manifestations, defines a sharper element of difference from scarlet fever and measles than any other symptom of the disease, as even in scarlet fever, in mild cases, the soreness of the throat is but little complained of, and in measles is not commonly found.

A peculiar feature of the throat trouble, in cases of any gravity, is the great enlargement of the tonsils, and this, too, out of proportion to other evidences of disease, aggravated, when it goes to this length, by a more or less severe bronchial trouble. The tongue is generally red, with a thin, solid, yellowish or brownish coating, differing from the white-coated and red-pointed tongue of scarlet fever.

In rötheln the pulse is less frequent by far than in scarlet fever of like grade, and ordinarily less than in measles; neither is the temperature as high, for in a limited observation I have never found the temperature to exceed 103°.

The process of desquamation is much as in scarlet fever, though of longer duration, and the scales are not so large, being mostly of a fine branny character, save on the hands and feet.

Cause and Propagation.—What atmospheric and terrene conditions are needful to the development of this disease has not yet been satisfactorily determined, as but few months have elapsed since it first made its appearance in Sumter county, never having been seen before this year, 1880, by any of the physicians now practicing in the county. At the time of its first appearance with us, about the early part of April, there had been a continuous rain-fall, not so excessive in quantity, but constant, with a thermometer higher than the average. We have here the two factors of heat and moisture present on its first appearance, and prolonged for a sufficient number of weeks to delay the usual farm work.

No traceable history of contagion could, with the greatest care of investigation, be found in the first two cases that made their appearance. Those that followed were propagated by the subtle element of contagion, the period of incubation being from five to twelve days. The disease is less contagious than measles or scarlet fever, and has no objective point in its selection

of tenants, affecting white and black alike, with the same general course of symptoms and after consequences.

Treatment.—In mild cases but little medication is needed. In order to meet the throat trouble, give an adult one tablespoonful of a saturated solution of chlorate of potash every three hours, acidulated with ten drops of tincture of iron. In connection with this, three to five grains of sulphate of cinchonidia or quinine may be given every eight hours, as an antipyretic and antiseptic. I have also prescribed with the quinine or cinchonidia, omitting the potash and iron, the sulphite of soda as an anti-zymotic, every three hours, in thirty grain doses, dissolved in sufficient water, reducing the dose if it purges too freely.

In every case, infant or adult, where the secretion of tenacious mucus became constant and distressing, and where the tonsils were enlarged and made swallowing and respiration difficult, I used, in connection with the above specified treatment, the prescription of Dr. Pritzinger, of Pennsylvania, for tonsillitis, which, for many years, and in hundreds of cases, I have employed with the same confidence of breaking up a tonsillitis in its formative stage as I have of averting a malarial chill with the preparations of Peruvian bark, as follows:—

℞.	Potassii chlorat. pulv.,	gr. lx	
	Spt. æther. nit.,	f℥ iv	
	Tinct. guaiac.,	f℥ xij.	M.

Sig.—Dose for adult, teaspoonful, undiluted, every three hours. Shake well. In properly reduced proportion for children and infants. Follow each dose with a few swallows of water.

Beyond this, nothing suggests itself in the management of the general run of cases. Peculiar conditions are to be met as they arise. The nourishment during the height of the disease must necessarily be in liquid form, milk and soup, as the difficulty of swallowing renders solid nourishment inadvisable. It is well to be suitably clothed, to avoid draughts, and during the period of desquamation, to abstain from any unusual causes of stimulation, excitement and fatigue, as there is danger of crippling the kidneys in their work of eliminating the waste of the system.

In rötheln, as in all diseases of its class, the physician must watch his cases closely, and drive his medication, with ready hand, well up to all the requirements. By so doing, the very large proportion of his cases will run their due course to convalescence, and after complications will be avoided.

A PLEA FOR A MEDICAL AID ASSOCIATION.

BY FRED. HORNER, M.D.,

Of Salem, Va.

In the number of the Medical and Surgical Reporter for October 14th, 1876, the question of the organization of an American Medical Brotherhood was briefly discussed and commended; that this subject has during the interval engaged the attention of the profession, the following facts will show.

In 1876, under the auspices of the Philadelphia County Medical Society, an Auxiliary Aid Society was founded, and has been nobly sustained by the efforts of Drs. H. H Smith, Benj. Lee and W. R. D. Blackwood. Ere long this Society will have a handsome and permanent fund, the profits of which promise to secure a respectable amount for distribution to the families of deceased members. The profession in the city of New York have also undertaken a like philanthropic work. Dr. James Anderson is the founder of this society. In the 12th annual report, the president, Dr. Blumenthal, states the permanent fund to be $6254.55, which is deposited in the best saving bank of the city. Since its organization $20,000 has been distributed for the benefit of the widow and orphan. Dr. Blumenthal adds, in his late report, "The amount of comfort conferred and grief and sorrow assuaged by this sum, surely no figures can adequately express." The State Medical Society of Virginia has given its cordial support towards the completion of a Medical Aid Association, whose aim shall be "to obviate the more expensive methods of life insurance, and to assure prompt assistance to the unfortunate, especially to those who have neglected, or are unable to incur the expense of regular insurance." The Mutual Benefit Association of Kentucky, originally undertaken by prominent physicians of that State, requires an admission fee of $10, and the payment of an annual fee of $2, which secures to the family of a deceased member $2500, or to one sick $5 per week, for serious illness or accident. The writer has sought, by correspondence with brother physicians, to elicit from them an expression of opinion on the practicability of an Aid Association for the benefit of the profession of this country. They will pardon the liberty which is herewith assumed, to quote from their letters.

The late President of the American Medical Association, Dr. John Hodgen, of St. Louis, says: "I shall at all times and on all occasions

be pleased to do anything in my power to aid the widows and orphans of deceased members of our profession."

Professor L. A. Sayre: "It is a noble object, and deserves the favorable consideration of every man in the profession. The plan has worked admirably in this city, and would be very good to model after."

Professor N. S. Davis: "The object in view is a good one. Many years since I advocated such an organization, and bestowed upon the matter some thought."

Dr. Blackwood: "We are fully in accord with the effort to establish both a State and National Medical Aid Society. It only requires concentration, to get the matter under way."

Dr. Wendel, Murfreesboro, Tenn.: "Right here in this town we have an instance of an excellent physician who, after forty years' practice, died, and his children are left penniless, and his widow's home was sold last week."

G. B. Thornton, President of the Board of Health, Memphis, Tenn.: "Had not the noble and generous physicians of the city of New York sent us money, during the pestilence of yellow fever in this city, many families of physicians who died would have suffered deplorable want."

Dr. James Anderson, of New York: "Our Association has been of great comfort to many a widow. Yea, and four of the members of it, one a Professor, and one who drove two horses. This Association excites sympathy and affection."

Shall it be deemed extravagant and premature, on the testimony above produced of its acceptance by prominent physicians of various sections of this country, and in view of the fact that in Metropolitan cities, and in several States of the Union, the medical societies have considered the question to be eminently practical, to urge upon the attention of the members of the American Medical Association, possessed as they are of wealth and influence, to make it one for their consideration, and to give their moral support to such an undertaking? It is a matter of surprise that during the long and eventful career of the National Association, during which time they have contributed to the attainment of a high standard of medical education, and annually conferred upon plans for the relief of their fellowmen, and have saved hundreds of lives, they have failed to devise any plan of a benevolent character for the relief of their medical brethren, who furnish no exception to the accidents, financial distress and ills referable to the chances of human life. The creation of a Section of Benevolence would help to accomplish this result. In the words of the gifted Atlee, "Our profession should ever seek, along with the advancement of medical lore, to promote every system of benevolence and humanity." It was asserted, with truth, on the occasion of the late meeting of the Sanitary Association at New Orleans, that "the legislatures of the several States of our Union leave no doubt that every child among us inherits the right to an education, the right to proper food, clothing and shelter." Will physicians in this land practically deny these rights to the families of their brethren? Should we not seek to dispense our own charities and to control the funds raised, rather than commit them to corporations which tax the policy-holder, and after all, may fail?

Physicians who will contribute of their abundance, toward a Medical Aid Association, with the generosity which marks the lives of thousands, north, south, east, and west, of other callings and professions, will thereby rear to themselves, in the hearts of a grateful posterity,

"Monumentum aere perennius
Regalique situ pyramidum altius."

CARIES OF THE CUBOID—REMOVAL OF THE DISEASED BONE AND RECOVERY.

BY REUBEN A. VANCE, M.D.,
Professor of Operative and Clinical Surgery in the Medical Department of Wooster University, Cleveland, Ohio.

The following case came under my care in 1873, and was operated upon in 1874. The simple character of the measure adopted for the relief of this patient will serve to show that such cases can be radically cured by other operative procedures than those which require the sacrifice of either the foot or leg.

Miss L. S., aged twenty-one, was injured on the outside of the right foot, in 1871, by the fall of a flat-iron. For several days the foot was swollen and tender, but by the end of a month the part seemed entirely well. Nothing further was noticed until some time in 1872, when, after dancing late one night, a violent pain located itself at the site of the injury. If the patient used her foot in any way, this pain became more intense; rest, with elevation of the part, alone secured a mitigation of her sufferings. The foot slowly enlarged; abscesses formed above and on the outside of the part, and were converted into permanent sinuses. As time passed the acute character of the symptoms disappeared, and the part could be moved without uneasiness; if the patient placed her foot on the floor and bore any weight upon it, a sickening, rather than severe

pain was evoked, which persisted for hours. This pain recurred at night—seemingly provoked by unconscious movements in sleep—and was the chief complaint of the patient. There were two openings upon the top of the foot, and two upon its outer side. By passing a probe into these sinuses it was discovered that they all led to the outer and lower side of the tarsus, in the immediate region of the cuboid. Three out of the four canals could be demonstrated to communicate with carious bone ; in the fourth sinus —situated just in front of the outer malleolus— the probe could not be made to reach the bone. At its largest point the right foot measured two and one-fourth inches more in circumference than the corresponding part of the left. An attempt to bear the weight of the body on the right foot excited pain ; pressure over the cuboid likewise did so; other movements of the part, which involved no direct compression of the region of the cuboid, were painless. There were no evidences of either pulmonary or cardiac disease in this patient ; no hereditary tendency to strumous or rheumatic affections ; and as the patient was anxious to get well, I advised an operation for the removal of the diseased bone. To this measure the patient and her friends finally assented, and the operation was performed October 24th, 1874. After the patient was anæsthetized an incision from the base of the fifth metatarsal bone to the anterior border of the outer malleolus was connected with one running from the base of the fifth metatarsal two inches inward and forward. When the flap thus formed was reflected, the sinuses could be traced to their origin in the carious cuboid. At this point the only real difficulty in the operation was encountered ; this arose from lack of proper appliances to seize and retract the tendons of the peroneus longus and peroneus brevis. Dr. Needham finally succeeded in holding them out of the way while I onnected the openings in the periosteum and exposed the carious bone ; this accomplished, the substance of the cuboid was broken up and extracted piecemeal, its periosteum and ligaments alone remaining. A careful examination of adjacent parts showed the disease to be limited to the cuboid. After the carious bone was removed the tendons of the peronei were returned to their original situation, drainage tubes were inserted and the foot and ankle were fixed in a plaster-of-paris splint. An opening at the most dependent portion of the wound permitted free drainage and enabled the attendants to wash out the latter with a solution of carbolic acid— one to fifty—without disturbing the immovable apparatus in which foot and ankle were embedded. Six weeks elapsed before the plaster splint was removed ; at the end of that period the site of the excised cuboid was occupied by a mass of adventitious tissue, and although the wound was not completely cicatrized, yet the cavity was filled and the granulations at the surface were healthy. The foot and ankle were again rendered immovable, but the patient was permitted free exercise on crutches ; by the end of a fortnight the wound had healed.

In July, 1880, I saw this patient and made a careful examination of the foot. The right foot measured the same as the left ; within an eighth of an inch of absolute equality in every measurement. She says that since her marriage she has done all her own housework, with the exception of a month before and a month after the birth of her child. The latter was born in 1879, nearly three years after marriage. While carrying this child she was annoyed by occasional pains in the tarsus. There was also some irritability of the scar a short time prior to her delivery. At this time her husband wrote me a very full and precise account of her symptoms, and, with the impression that the congestion of the lower extremities incident to the latter stages of pregnancy was the cause of the pains, I advised her to give up her domestic duties and keep the recumbent posture as much as possible. She assured me that so long as she complied with this advice she suffered but little pain ; the latter, however, left her permanently with the birth of her child.

The foregoing case illustrates the simple measures that occasionally suffice for the cure of certain forms of caries of the tarsus. In connection with others that have been operated upon by the writer, the clinical features of this patient's history might serve to illustrate certain phases of modern surgical practice in dealing with diseases and injuries of the human foot. Notwithstanding the readiness with which this carious bone was excised, and the speed with which the patient recovered, the friends of the latter were assured, by respectable surgical authority, that any operation short of amputation was mere reckless experimentation ; that blood-poisoning would surely supervene if the dead bone were gouged out, and that no surgeon with an established reputation would advise any other measure than amputation.

—In Sweden and Denmark, sheep's milk is generally used ; in Switzertand, goat's milk ; in Lapland, reindeer's milk ; and in Tartary mare's milk.

Hospital Reports.

WESTERN PENNSYLVANIA HOSPITAL.

SERVICE OF W. H. DALY, M.D.

Reported by George W. Hiett, M.D., Resident.

Two Cases of Typhoid Fever—No. 1. Peritonitis, Abscess of Liver, Pneumonia, Death, Post-mortem Examination. No. 2. Abscess of the Neck—Recovery.

Joseph E., admitted November, 1881, aged twenty-four, single, laborer, born in Switzerland; has been in this country but a short time; does not speak English (no family history; no previous sickness or injury); has always been strong and well, until the present illness.

October 30th. 1881, patient was taken sick, suffering from frequent diarrhœa, pain in the abdomen; this being the most prominent in right iliac region; loss of appetite, with considerable pain in the back and shoulders. Preceding this he suffered from minor ailments for a brief period; was able to be about, but quite disqualified for active duty. When admitted was very weak, requiring assistance of nurses to be conveyed to the ward; medium height, well developed, light complexion, skin smooth, no sudamina, or typhoid fever spots, belly not tympanitic, tongue coated, not very dry. Patient would speak when addressed by an interpreter, but seemed more or less reticent and stupefied. Was nervous, with slight twitching of the muscles. Pulse 92. Temperature, taken in the axilla at 7 P.M., 103⅗°.

Ordered the iodine mixture—

℞.	Potassii iodid.,	℈ iv	
	Iodinii,	gr. x	
	Glycerinæ,	f℥ ss	
	Aquæ,	f℥ ss.	M.

gtt. v in tablespoonful of water every three hours. The diet was restricted to a moderate quantity of beef tea and milk, given at regular intervals.

November 2d, patient rested well during the night; had one stool, which was examined and found to be of liquid consistence, and of a light brown color, tinged with yellow.

During the next five days temperature did not rise above 103°, and the lowest record was 100½°, till morning of the 7th, when it fell to 100°. In the evening the temperature rose 2⅗°, and at 8 P.M. about half a pint of clotted blood was discharged from the bowel, which floated in a thin, bloody fluid, nearly a pint in quantity. Administered gallic and tannic acid, āā, gr. x, and kept the patient absolutely quiet, on his back, in bed. 11 P.M., had another larger hemorrhage from the bowel, probably, two-thirds of a pint of clots. Belly not tympanitic, pulse feeble, not very rapid, and quite distinct. Ordered gtt. xxx, oil of erigeron, in emulsion, the dose to be repeated in two hours.

At 6 A.M., 8th instant, and at 3 P.M., there was a recurrence of the hemorrhage, but at each time very slight. After each attack a small dose of oil of erigeron was given. Morning temperature 97⅘°, pulse 104°, quite feeble. Gave milk punch f℥ j, every hour, till four ounces were taken, the patient getting in this amount f℥ j of whisky.

Prior to setting in of hemorrhage, on the 7th, the stools numbered from one to four in the twenty-four hours. They contained no trace of blood; were in character like the one described above. Temperature arose in the evening to 101⅘°.

November 9th. No recurrence of hemorrhage; circulation improved; temperature 101°; ordered milk punch, given every three hours—f℥ j. Prescribed carbonate of ammonia, gr. iij, and quinine gr. ij, in emulsion, every three hours, the iodine mixture being discontinued the 7th inst. Patient had a cough, which was not a very prominent symptom, and there was no lung trouble present, except a slight bronchitis. Evening temperature 103°, pulse 95.

Nov. 10th.	Temperature	100½°	; pulse	88 M.
"	"	102⅖°	; "	91 E.
" 11th.	"	98½°	; "	78 M.
" "	"	100⅘°	; "	86 E.
" 12th.	"	98°	"	80 M.

At this date bowels were moved for the first time since the 8th inst; stools contained no blood; patient very anæmic, but taking a good quantity of nourishment.

November 13th, 5 A.M. Hemorrhage again occurred; several small clots being discharged from the bowel with the stool; administered a single dose of the oil of erigeron. 9 P.M. a recurrence of the bleeding ensued, and in larger amount than at morning. Ordered gtt. xxx of the oil of erigeron, every hour, until four doses were taken. Instructed nurse to keep patient absolutely quiet, on his back, in bed; pulse not rapid, but regular and small; belly flat; tongue coated, but not dry; features pale, with sweat standing on the forehead; skin and extremities moderately warm. From this time to the 16th, inclusive, patient had one evacuation of the bowel daily, the passages resembling the usual typhoid fever stool, and presented no trace of blood.

Up to the 22d patient's condition had apparently changed for the better. There had been no hemorrhage since the 13th; he had gathered strength; a usual quantity of nourishment had been taken, and was well borne by the stomach. Plenty of sleep aided materially in restoring the vital functions. Just now, however, the diarrhœa became a troublesome symptom, the passages increasing in number from two in the twenty-four hours to five or six during the same interval. No blood was present in any of these evacuations.

November 27th. Diarrhœa continued unabated and at times became much worse; the passages, numbering from eight to twelve in the twenty-four hours, were watery and of a dirty green color. Prescribed chalk mixture with paregoric and tincture of kino.

November 29th. After repeated doses of the above drugs, as well as a resort to other remedies, the stools still continued frequent and copious. Patient gradually growing weaker, and complained of considerable abdominal pain.

December 2d. Pulse small and frequent; marked abdominal tenderness with slight tympanites; vomiting at frequent intervals; diarrhœa still profuse.

Examination of chest anteriorly revealed no abnormal condition, save increase in frequency

of the breathing. Patient too feeble to be raised up or turned from side to side in bed, and an examination of posterior region of chest was not made.

The temperature went up, on the morning of December 1st, from 101⅕° on previous evening to 103⅘, pulse 140, this temperature being one degree higher than at any previous time since admission. The morning temperature of December 2d was 101⅘; the previous evening it had declined to 101⅘, and on the evening of the 2d, it continued to fall, the thermometer registering 99⅘°. Ordered a turpentine stupe applied to the belly and the administration of food per enema for twenty-four hours.

December 3d. Very rapid breathing, small, feeble pulse, extremities cold, features presenting a dusky hue. Patient evidently fast sinking. Morning temperature 103½°, pulse 144. Discontinued all medicines, and endeavored, as far as possible, to relieve the sufferings of patient, until death should supervene. This occurred at 4 P.M.

Post-mortem examination, eighteen hours after death. Body greatly emaciated, skin somewhat discolored, lips cyanosed, abdomen distended, rigor mortis slightly marked, eyes and cheeks deeply sunken. Peritoneal cavity contained pus; intestines distended with gas and bathed in the purulent fluid; their walls intensely congested at various points, thickened and softened, presenting evidence of previously existing inflammation. In the small intestine there was no ulceration of Peyer's glands and no appearance of ulceration in the mucous membrane of the gut throughout its entire extent. Large intestine bound fast at several points by bands of adhesion. No perforations observed. Extensive and deep ulceration of this gut, from the anus to the ilio-cæcal valve, the latter being also involved. Some of these ulcers were transverse, some longitudinal, some round, and all of them deep; in size varying from half an inch to two inches in their greatest dimension. The cæcum and the ascending colon presented most extensive evidence of disease, but the ulcers were very numerous in the rectum and every other portion of the gut. Some had their edges rounded and sloping, denoting a tendency to heal, others presented ragged and deep margins, indicating total failure in the reparative processes. The quantity of fluid in peritoneal cavity not large, probably half a pint. Liver slightly enlarged and adherent to the diaphragm, its convex surface covered with pus. Gall cyst moderately filled with bile. External to it on the concave surface of the liver, and near its anterior edge, was a pus secreting surface about one inch and a half in diameter. This diseased area was deeply cupped and discharged its pus into the peritoneal cavity. A perpendicular section through the organ at this point disclosed the presence of a large abscess area of a more or less rounded form, and measuring three inches in diameter. In appearance it was a grayish, cheesy, friable mass, its border sharply defined from the surrounding normal liver substance. The mass of abscess occupied the anterior portion of the right lobe. Repeated section of the organ failed to reveal other points of suppuration or of deposit. Spleen enlarged and congested, only moderately softened. Kidneys slightly softened, the capsules adherent at certain points. Neither the spleen nor the kidneys contained points of abscess.

Left lung grown fast to the diaphragm and pericardium, with a few bands of adhesions connecting the outer lower portion of the lung with the chest wall. The lower lobe and the posterior inferior portion of the upper lobe were engorged, blue on the surface, heavy, the fissure obliterated by adhesions. Apex and anterior margin of lung intact. No evidence of tubercle. From the cut surface of the engorged portion no blood exuded, but a dirty brown non-aerated fluid could be expressed. A cube of this tissue thrown into water displaced its own bulk of liquid and floated beneath the surface. Early stage of acute lobar pneumonia. Right lung presents similar lesions, but less in extent, only the lower lobe being involved, and the adhesions between its base and diaphragm less firm than upon the left side. The fissures were not obliterated by bands of adhesion.

Pericardium contained above the normal quantity of fluid, and did not present evidence of previous inflammation. Left ventricle firmly contracted. Valves normal, but patulous, the auriculo-ventricular openings being filled with ante-mortem clots, which were firm and projected into ventricle and auricle.

The patient's death was caused by exhaustion consequent upon the extensive peritonitis, and latterly upon the sudden development of pneumonia. The former disease was set up by sloughing of the capsule of the liver (under surface) into the peritoneal cavity. The pneumonia was very recent, being developed probably during the twenty-four hours prior to death. The rapid breathing was due, in part, at least, to the peritonitis, and the latter, no doubt, stood in a causative relation to the development of pneumonia. The abscess probably bore some relation to the extensive ulceration of the large gut, being due to septic absorption from the ulcers. The adhesions between the pleuræ were old, at least in part. The temperature chart, character of the stools early in the disease, marked tenderness in right iliac region, appearance of the tongue, together with other phenomena mentioned, indicated the presence of a profound constitutional trouble.

The diagnosis of typhoid fever was probably the correct one. Absence of involvement of Peyer's patches militates against this view, but exceptional cases are recorded, in which the lesions of typhoid fever were confined exclusively to the large intestine.

CASE 2.—George L., aged 25, single, born in Germany, laborer, was admitted November 17th, 1881. Had not suffered from previous sickness or injury; temperate, and possessed a strong, rugged constitution; began, 7th inst., to complain of weakness in the knees, diarrhœa, epistaxis, pain in the bowels, loss of appetite, and cough; restless; unable to sleep at night; chills supervened.

Examination disclosed the presence of numerous typhoid fever spots on chest and abdomen; marked iliac tenderness; no tympanites or sudamina; tongue large, dry and coated; sordes collected upon the teeth. Later in the disease

delirium, tympanites and cough were the prominent symptoms. Following these, abscess of the neck, with profuse suppuration, proved a complication of grave import.

December 1st. Observed a swelling, size of a hickory nut, situated over the body of the inferior maxillary bone, which does not fluctuate.

December 5th. The swelling mentioned has disappeared. A lump about as large as a walnut is seen in the side of the neck, to the left of the larynx, and one inch above the sternal extremity of the clavicle. There is severe pain in the region of the tumor, the larynx is pushed toward the right side, the voice is husky. The skin over the point of induration presents no redness or other abnormal character, save slight tension, the heat of the part not appreciably greater than that of other parts of the body's surface. The tumor would move with each pulsation of the carotid, but the sensation imparted to the hand when laid over the entire area was not that of a general upheaving of the mass, as is observed in aneurism. It was decided to wait a few days, and in the meantime apply a flaxseed poultice, medicated with laudanum, in order to diminish the pain of the part.

On December 10th obtained fluctuation in the tumor, which was quite distinct, but evidently deeply situated. Larynx pushed considerably to the right of the median line of the neck, impairment of the voice more decided, patient being able to speak only in a faint whisper. It was thought proper to test the nature of the fluid underlying the integument, and considerable of the structures beneath it, and accordingly a clean hypodermic needle was thrust into the swelling at the point of easiest fluctuation, viz, in the angle of junction of the inferior portions of the sterno-cleido-mastoid muscle. The needle descended to a depth of an inch and drew off a sufficient quantity of fluid to judge of the contents of the sac. The liquid thus obtained had the appearance of laudable pus. An incision through the integument was made, about an inch above the clavicle and external to the position of the carotid artery. A small director was then used to effect an entrance into the sac. This gave vent to the pus, but it was necessary to make a free opening, in order to remove all resistance to the flow. This was done with a curved probe-pointed bistoury. Evacuated about four ounces of pus, which was tinged with blood. Patient experienced immediate relief, both from the pain of the swelling and the pressure upon the larynx. The sinus was kept open by a carbolized tent of oakum. The medicated poultices were continued at intervals of six to eight hours. The cavity continued to discharge healthy pus until January 5th, at which time the pus cavity and its outlet were almost entirely healed. Patient was discharged from the ward Feb. 2d, 1882, cured.

This case was one of the severer forms of typhoid fever received into this hospital, aside from the complication spoken of. The latter is the only instance of the kind noted among the many cases of typhoid fever admitted here.

The deep-seated character of the suppuration, its proximity to the large blood vessels of the neck, and the question of diagnosis, occurring in a person professedly disturbed by the ravages of a severe typhoid fever, are considered points worthy of special notice.

Editorial Department.

Triplets (Prolonged Labor).

In the *British Medical Journal*, Dr. J. Howe records the following case:—

A few days ago I was called to attend Mrs. M., aged 34, in her third confinement. The two children by her former confinements are aged four and eight years respectively. At 10.30 A.M., the nurse who came for me stated the "child's feet and body were in the world for some time," and on going to the patient, I found it so, and delivered in the usual manner. From the long-continued pressure on the umbilical cord, the child was almost asphyxiated, and I adopted Sylvester's method for resuscitation, together with stimulation to the spine, and it gradually revived. On returning to the mother to examine the uterus, I found the head of a second child presenting above the brim of the pelvis, which was also distinctly felt through the parietal wall; but there were no indications of a second labor. I watched her closely all day, waiting the course of events, and toward night, finding the "pains" were not returning, I administered a drachm of the liquid extract of ergot; this did not produce the slightest effect, and there being no immediate symptoms of danger, I decided upon leaving nature to take its course, sustaining her strength with nourishing food and stimulants. At 12 P.M. she complained of aching pain in the back, for which I prescribed a draught containing thirty minims of tincture of opium, after which she had a good night's rest, and was altogether relieved from pain until 1 P.M. next day, when she again complained of the same pain, which now more resembled the commencement of true labor-pains, and continued so till about 4 P.M., when I thought it advisable to administer another drachm of ergot. Soon afterward, the pains increased in severity, until the head of the second child presented close to the outlet of the pelvis. She then had violent bearing-down pains for some time; but the head remaining still in the same position, and the patient getting weak, I applied Simpson's forceps, which are the ones I always use, and delivered the child at 6 P.M.

On again examining the abdomen, I found that, although it was very much diminished in size, there was still sufficient enlargement to lead

me to believe there was another child; and on making a vaginal examination, I found the head of the third presenting. This one was delivered naturally by three or four expulsive pains, and for some time after birth I thought life was extinct; but after adopting the usual methods for artificial respiration, and placing the child in a hot bath, which I think was of the greatest service in this instance, it soon revived.

I kept up the uterine contractions for some time; but finding they were not sufficiently strong to expel the detached placenta, I extracted it in the usual way. There were two distinct placentæ, united by a thin, membranous band; one of these, somewhat the larger of the two, furnished the supply to two of the cords. The first and third child weighed each six pounds, and the second six pounds and a quarter.

Hernia of the Ovary.

At a recent meeting of the Royal Medical and Chirurgical Society (*British Medical Journal*). Dr. Robert Barnes said that scanty advantage had been taken of the opportunity which the ovary, brought to the surface of the body, offers for physiological observation. He cited in abstract some of the most marked cases of hernia of the ovary which have been published, notably those of Goucy, Pott, Desault, Lallemand and Poquet, Deneux, Veboux, Cæsar Hawkins, Oldham Holmes, Coote, Œttingen, Meadows and Lawson, Courty, Leopold, Beigel, Boinet, Rheinstädter and Raffo, and related two cases observed by himself. 1. The patient, a single woman, aged 41, had always enjoyed good health. At 24 she sustained a rupture in the left groin and wore a truss; at 38 she observed a second swelling behind the first. The swelling and tenderness of the ovary were observed before and during the menstrual periods. Corresponding sphygmographic observations showed distinct rise of tension preceding the flow, and subsiding when the flow set in. The ovary was removed. A description and illustration of it were submitted by Dr. Goodhart. Dr. Barnes referred to Dr. Chambers' case in the *Obstetrical Transactions*, in which bodies simulating ovaries turned out to be testicles. He discussed the etiology of hernia of the ovary and uterus, citing Cruveilhier's views. He referred to the frequent complication of anomalies of development of the genital organs in association with hernia of the ovary; also with extra uterine gestation. He enumerated the varieties of hernia of the ovary, and referred to the supposed greater frequency of inguinal hernia when the ovary was concerned; to the greater frequency of congenital hernia; the complications with intestine and epiploon; the dependence of hernia of the uterus upon preëxisting hernia of the ovary, citing Cruveilhier's theory and the confirmatory conclusions of Puech, Deneux, and Cæsar Hawkins. He then discussed physiological points, illustrated by the observation of the herniated ovary; how the ovary swelled concurrently with increased tension of the vascular system before menstruation; how the round ligaments swelled. He discussed the order in which the phenomena of menstruation occurred, arguing that the ovarian nisus was the *primum mobile*, that nervous and vascular tension followed, and lastly, the menstrual flow; resting greatly upon sphygmographic observations. He suggested that the recent practice of oöphorectomy on Battey's principle would supply opportunities for deciding this and other questions; and proposed that sphygmographic observations should be made upon the subjects of this operation. He then discussed the diagnosis and treatment of hernia of the ovary, contending that it furnished a legitimate motive for Battey's operation *quoad* this affection at least. The paper was illustrated by sphygmographic tracings, by drawings of the amputated ovary, and by a cast of the parts.

Dr. Routh said that such cases as those described by Dr. Barnes were important, not only as indicating the symptoms of ovarian hernia, but as contributions to the history of menstruation, which no doubt began in the ovary. He had, however, observed some symptoms to which Dr. Barnes had not referred, in cases in which the ovary had fallen into Douglas' pouch; especially on the left side. In one case, that of a young lady, who had a displacement of the ovary into the left side of Douglas' pouch, where it had become adherent, pressure on the ovary caused sexual excitement. This, if observed in hernia of the organ, would be an additional means of diagnosis. Another symptom observed in these displacements was, that pressure on the ovary produced a feeling of sickness like that arising from pressure on the testicle.

Mr. Hulke said that cases of hernia of the ovary were rather frequently met with by surgeons. Of course, care was necessary in making a diagnosis. In 1871, 38 cases of hernia of the ovary were recorded and classified by Englisch of Vienna (see *Biennial Retrospect* of New Sydenham Society, 1871-72). Of these, in 27 the hernia was inguinal; and in 9 of these the displacement was on both sides. In most of the inguinal cases the hernia was congenital. As regarded the absence of any process of peritoneum in one of Dr. Barnes' cases, this might have existed and have become atrophied. In congenital cases, it appeared that the ovary was almost always accompanied by the Fallopian tubes; while, when the hernia was acquired later in life, the ovary generally came down alone. In many of the recorded cases, a distinct tubular process of peritoneum was described. As regarded operation, each case must be judged on its own merits. He had seen cases where a lightly fitting truss produced no discomfort to the patient, while in others it could not be borne.

Mr. Langton referred to the difficulty of diagnosis. At the Truss Society, among more than 4000 cases of inguinal hernia in women, there were 67 cases of hernia of the ovary. Of these, 42 were congenital, and in 25 the displacement occurred at various ages. The ovary was reducible in 29 of the congenital cases, and in 27 of these the patients were quite relieved by the use of a truss; the other two did not report themselves, and were probably cured. Of the cases in which the hernia occurred later, 8 were reducible and 17 irreducible; the proportion being the reverse of that in congenital hernia. The conditions of the ovary during the menstrual pe-

riods varied. In some, there was swelling of the ovary with effusion of fluid, which became absorbed; but when the hernia had been first observed between the ages of one and twelve, no such excitement of the ovary was developed. The application of a truss gave relief in most cases; in none were there any indications for operation.

Dr. Heywood Smith said that it was very rare to find sexual excitement produced by pressure on the ovary; pressure generally caused pain of a sickening character. Might not the sexual excitement in Dr. Routh's case have been caused by irritation of the pudic nerve, in consequence of the adhesions to the pelvis?

Dr. Barnes thought that the remarks of Mr. Hulke and Mr. Langton tended to confirm the opinion of Cruveilhier, that most cases of hernia of the ovary were congenital, and that the displacement was most frequent on the left side. He had not met with any cases in which distinct sexual excitement was produced by pressure on the ovary. He thought that the greater frequency of displacement in Douglas' pouch on the left side was caused by the round ligament and the ovary being more lax there than on the right.

Extraction of Teeth in Pregnant Women.

At a recent meeting of the St. Louis Medical Society (St. Louis *Medical and Surgical Journal*) this subject was under discussion. Dr. Borck asked, "Is it advisable to allow the extraction of a tooth or of teeth in a woman who is pregnant. I have been several times asked this question by dentists. Some eminent dentists are afraid to extract an aching tooth in a pregnant woman, lest it may cause abortion."

Dr. Green said that it does not necessarily produce abortion. Of course, there may be cases where such an effect would follow, but if the woman is suffering, and cannot be relieved by any other means, he would recommend the extraction of the tooth.

Dr. McPheeters said that there is a form of toothache which is sometimes a symptom of pregnancy. The teeth are sound, and, of course, it would do no good to extract them. He would not hesitate to advise the extraction of a carious tooth.

Dr. Hughes said, "Some patients, when pregnant, are extremely hyperæsthetic; the hyperæsthesia extends to the branches of the fifth pair. Other women, who are more or less nervous when not carrying a child, seem to possess more nerve than at any other time. I do not know, in view of the varying and variable physiological condition in which we find women in the pregnant state, that we could arrive at any definite rule applicable to all cases. It is simply a question of individual temperaments, of conditions of the patient, and of the existence of centric or eccentric irritation; the existence or non-existence of central or peripheral irritation. And, if a pregnant woman is extremely hyperæsthetic, and you can find a focus of origin for it in the peripheral irritation of a decayed tooth, there would be no impropriety, in the majority of cases, I apprehend, in the removal of that decayed tooth. If in a condition of general nervous excitation, especially if centered in the brain or cord, you have any form of spasmodic display, and you find a possible peripheral source of the irritation, I think the general sentiment of the profession would concur in the propriety of removing that possible source of peripheral irritation."

Dr. Jonaston said, "Some years ago I was called to a lady who had been married six or eight weeks. The second left molar was decayed and an abscess was forming, and protruded from the root of the tooth. The abscess was painful and I advised opening it. She consented and I took my lancet and opened the abscess. This produced a tremendous shock, and in 24 hours she aborted. This case occurring in my early practice has made me very careful about extracting a tooth from a patient during the early part of pregnancy if she were of a nervous temperament; it is a hazardous practice. But if the toothache continues, the reflex irritation of the pneumogastric nerve, connecting with the great sympathetic, may induce uterine contraction, and cause the woman to abort. In such a case we should recommend that the tooth be pulled. There is no rule in the practice of medicine; and no rule as regards drugs, except castor oil. I have given calomel for 20 years, under the supposition that it acted on the liver, and now we are told that it doesn't act upon the liver at all."

Dr. Hurt closed the discussion by saying, "I think we are all obliged to concede the possibility of the extraction of a tooth during pregnancy producing abortion under certain conditions. There is no doubt, also, that there are circumstances under which the extraction of a tooth during pregnancy ought to be advised. The loss of a sound tooth ought not to be allowed unless something is going to be accomplished by it that cannot be accomplished otherwise. But I would have no hesitation about advising the extraction of a tooth from a pregnant woman if it was absolutely necessary to relieve her from a distressing, harassing pain that was wearing her out; and in doing this we may administer an anæsthetic without interfering in the least with the pregnancy. When she is under chloroform or ether we obviate the shock which is usually attendant upon the extraction of teeth. And experience has taught that pregnant women are very tolerant of these agents."

Remarkable Monstrosity.

Dr. Boisliniere recently presented to the St. Louis Obstetrical and Gynæcological Society (St Louis. *Courier of Medicine*) the following remarkable case which occurred in the practice of Dr. C. P. Smiley, of Potosi, Mo. The specimen was given birth by a mulatto woman, who had previously been in good health. When she was six months pregnant she fell across a door sill, which was raised above the floor, and struck upon the abdomen, and from this time the motions of the child, which had been perceptible before, ceased, or at least became very feeble. She was finally delivered, at full term, of this malformed fœtus. The mother was twenty-six years of age. There was no hereditary taint in the family. One leg is wanting from the hip, and there is no abdomi-

nal wall, and the stomach, duodenum, small intestine, mesentery and colon are without the abdomen. The colon is like a second stomach.

Dr. Coles was asked to say something about this case. He said: I have not had time to examine this specimen, and I shall not, therefore, address my remarks exclusively to the case in point, but make a few such as are suggested by it. Some two years ago I had a case in my own practice, in which a portion of the f rearm was missing, and also the occipital bone, and that suggested to me the question as to the causes of intra-uterine amputations and other physical defects in children. It is well known that Montgomery and Simpson hold the view that these intra-uterine amputations are generally due to the presence of bands of adhesions, or to the umbilical cord passing around the limb. Now if you will notice such cases, you will very frequently find that the deformity is multiple in character; that is to say, if a limb is missing, there is apt to be also a bone of the head missing, a defect of the jaw, lip, or some other deformity, as there is with this child; the entire limb here is missing, and the wall of the abdomen is also undeveloped. It is very hard to account for many such defects on the theory of constricting bands. Montgomery reports two cases of children who were born, one with the parietal and several other bones undeveloped, and also a portion of the lower jaw; the other had an ulna and the parietal bone missing. I think the cause of such deformities is more frequently an arrest of development from some centric cause—from a deficiency of autogenetic force, rather than of secondary mechanical origin.

Dr. G. A. Moses then said: In connection with this—although it does not properly belong to this class of cases, still it might come under it in connection with the constricting bands—I will mention a case which I have under observation; the case of a German girl who came here to have an inconvenient and painful congenital stump amputated. On the left leg is what appears to be an amputation of the foot just above the ankle, and about three inches above the stump there is what appears to be a constricting band; the skin appears to be in close coaptation with the bone, just as if a ligature were drawn around the stump. This has become very painful of later years, and she came to have it amputated. She has some defect of every limb on her body, either fingers or toes. besides this defect which I have mentioned. They are all congenital.

Epileptiform Seizures.

Dr. E. C. Spitzka records the following singular case (in the *American Journal of Neurology and Psychiatry*) of epileptiform seizures associated with imperative conceptions. "He was consulted last summer, by a man aged 39, a native of Germany, with reference to certain attacks. They began with sharp and almost painful formications in the finger-tips and feet, then followed a sensation of losing consciousness, against which the patient struggled, and which he overcomes, as he avers, by catching on firmly to some fixed object. Should the attack occur while he is eating, his arms, and particularly his hands, contract violently, so that it is impossible to take the knife or fork from him, while he, conscious all the time, experiences inability to loosen this grip. At times the ordinarily tonic spasm exhibits an illy marked clonic character. His wife states that while he says but little during this attack, which is of hardly more than momentary duration, what he says is rational, and connected with his mental processes, as evinced before and after the attack. He was seen in one of them. His ordinarily mobile and dilated pupils became more dilated while he described the tingling aura. He was made inhale a few drops of nitrite of amyl, to which he reacted readily, and he expressed himself that the fit was broken. With the tingling he had, on this occasion, a sort of sensation as if telegraph wires were strung around his body, accompanied by a "drawing" feeling. At other times an odor was perceived, such as musk, opium, gas, or as of a very cool fresh air. These attacks have increased in frequency of late years. As a young man he experienced a great many of them, but under treatment they disappeared, the patient himself claiming that cannabis indica did more good than any other drug. The patient has been married fourteen years; four years after his marriage he, as he now terms it, "imagined" that he saw his clerk make a signal to his wife, and based a suspicion of marital infidelity on this fact; which, however, he corrected a few weeks later, becoming convinced that he had been the victim of a delusion. Three months later he experienced imperative conceptions, in the shape of the idea that, if he turned his head rapidly, he would encounter a sharp piece of broken glass or a knife. Particularly when a horse in the street car rears its head, he cannot, struggle as he may, divest himself of the idea that its neck will be severed by a large butcher's knife. These ideas seize on his mind suddenly, startle him by their strangeness, and he reasons vainly against their absurdity; originally they were very painful to him; latterly custom has bred a tolerance, and they are less annoying. He was placed on ergot and bromide of sodium. and provided, with nitrite of amyl, against the return of any prodromata of an attack. For five days he was entirely free from any untoward symptoms, after which time he was lost sight of.

Death from Asphyxia in Phthisis.

W. Barrett Roué reports the following instructive case in the London *Lancet*:—

On May 3d, 1881, I was called to see a wretched, neglected looking boy, aged eleven years. The history was that of a cold resulting in some chest affection, for which he had had no medical advice. A constant cough and pain in the chest had been present for five months.

On my first visit I found him sitting up in bed, breathing rather rapidly, but not seeming much distressed, and in the act of expectorating much purulent sputum into a receptacle already nearly full. On physical examination there appeared to be no flattening or falling in of the chest on either side, but the respiration was shallow. There was marked dullness at the right apex, both in front and behind, and large, moist sounds

were heard over the upper portion of the same lung, accompanied by small crepitations. There was increased vocal resonance all over the remainder of the right lung. On the left side there was exaggerated breathing, which I considered to be merely compensatory, with slightly prolonged expiration. Otherwise the lung seemed healthy.

The boy was treated for cough, and an attempt was made to improve his general condition by the administration of cod-liver oil, milk and beef tea. In spite of this treatment, he steadily decreased in weight. The temperature varied from 100° to 104°, usually highest at night time. From this I considered the prognosis to be unfavorable, but did not by any means apprehend a very rapid or a sudden termination to the case.

On May 19th, while sitting up in bed, and without any severe cough, blood mixed with air began to well from his nose and mouth, and in about three or four minutes he was dead, as it appeared, simply from asphyxia, the trachea and bronchi being full of blood, which the boy was unable to expel.

Post-mortem examination.—Body much emaciated. Heart healthy; right side gorged with thick, black blood; left side empty. The right lung was solidified throughout, except a small portion of the extreme apex, and composed of degenerated, cheesy-looking material. There was a large, irregular cavity, about the size of a goose's egg or larger, in the lower part of the upper lobe, extending for a considerable distance into the lobe beneath. This cavity was situated more toward the posterior than the anterior aspect of the chest; indeed, there was scarcely any lung tissue left beneath the pleura in the former situation. The cavity was full of soft, recent blood clot, which passed into the communicating bronchus and upward toward the trachea. On removing the blood clot, an artery about the size of a crow quill was found severed, and the ends hanging down against the walls of the cavity, one on either side. This vessel, previous to its rupture, had evidently passed right across the cavity. The left lung was emphysematous, the air cells and bronchial tubes were full of blood, and a clot passed a considerable distance up the left large bronchus; otherwise the lung was healthy.

Remarks.—Up to the moment of the occurrence of the hemorrhage I think we have a fairly clear case of a condition which, for want of a better name, I will call "pneumonic phthisis." The little patient had probably suffered from an attack of pneumonia in the right lung, the products of which, failing to be absorbed, had broken down, and then gradual disintegration had caused the cavity. The important question is, What was the immediate cause of death? Two causes only, I think, are worthy of consideration, viz., syncope from loss of blood, and asphyxia. There is certainly a third possible cause in shock; but the difficulties of arriving at any reliable conclusions as to this condition in children when the physical signs of organic mischief are so decided as in this case, justify the little notice I have taken of shock as an agent of death. With regard, then, to syncope from loss of blood, the post-mortem evidence is certainly against it. In the first place, the condition of the body strikes us: the face was mottled and of a purple color; in death from syncope it is usually very pale. In the second place, the right side of the heart was gorged with blood; in death from syncope all the cavities are usually empty. Really, the patient lost very little blood, considering the rapidity of his death. Upon consideration, then, asphyxia seems to be the immediate cause of death suggested by the post-mortem examination, for the following reasons—

1st. The right side of the heart was gorged while the left was empty.

2d. The large and smaller bronchi in both lungs, and even the air cells in the sound lung, were filled with blood, so as effectually to cut off all communication between the air and the air cells.

3d. The face bore the mottled and purple hue so well known in cases of death from suffocation.

Impure Chloroform.
